#### 注 意

医学是一门不断发展的科学。由于新的研究及临床实践在不断丰富人们的知识,因此在药物使用及治疗方面也在谋求各种变化。本书编者及出版者核对了各种信息来源,并确信本书内容完全符合出版时的标准。然而,鉴于不可避免的人为错误和医学学科的发展,不管是编者、出版者还是其他参与本书出版的工作者均不能保证此书中的内容百分之百正确。因此,他们不能对由此类错误引起的后果负责。

我们提倡读者将本书内容与其他资料进行确证。例如,我们希望读者对他们将要使用的每一种药品的说明书仔细阅读,以确证本书的有关信息是正确的,且推荐的药品用量及禁忌证等没有变化。该建议对新药或非常用药尤为重要。

### Preface

This book is a concise review of the medically important aspects of microbiology. It covers both the basic and clinical aspects of bacteriology, virology, mycology, parasitology, and immunology. Its two major aims are (1) to assist those who are preparing for the USMLE (National Boards) and (2) to provide students who are presently taking medical microbiology courses with a brief and flexible source of information.

In this new edition, we present current, medically important information in the rapidly changing fields of microbiology and immunology. We have included updated information on such topics as human immunodeficiency virus, hepatitis viruses, and immunology. Our goal is to provide the reader with an accurate source of clinically relevant information at a level appropriate for those beginning their medical education.

These aims are achieved by utilizing several different formats, which should make the book useful to students with varying study objectives and learning styles:

- (1) A narrative text for complete information.
- (2) Summaries of important microorganisms for rapid review of essentials.
- (3) Review questions at the end of each chapter.
- (4) Sample questions in the USMLE (National Board) style, with answers provided after each group of questions.
- (5) A USMLE (National Board) practice examination consisting of 80 microbiology and immunology questions. The questions are incorporated into a clinical case format and simulate the computer-based examination. Answers are provided at the end of each block of 40 questions.
- (6) Clinical case discussions to illustrate the relevance of the material to patient problems.

In addition, the following specific features should be emphasized:

- (1) The information is presented succinctly, with stress on making it clear, interesting, and up to date.
- (2) There is strong emphasis in the text on the clinical application of microbiology and immunology to infectious diseases.
- (3) In the clinical bacteriology and virology sections, the organisms are separated into major and minor pathogens. This allows the student to focus on the clinically most important microorganisms.
- (4) Key information is summarized in useful review tables. Important concepts are illustrated by figures in color.
- (5) The 654 USMLE (National Board) practice questions cover the important aspects of each of the subdisciplines on the USMLE—Bacteriology, Virology, Mycology, Parasitology, and Immunology. A separate section containing extended matching questions is included. In view of the emphasis placed on clinical relevance in the USMLE, another section provides questions set in a clinical case context.
- (6) Brief summaries of medically important microorganisms are presented together in a separate section to facilitate access to the information and to encourage comparison of one organism with another.
- (7) Ten clinical cases are presented as unknowns for the reader to analyze in a realistic, problemsolving way. These cases illustrate the importance of basic science information in clinical decision-making.

After teaching both medical microbiology and clinical infectious disease for many years, we believe that students appreciate a book that presents the essential information in a readable, interesting, and varied format. We hope you find this book meets those criteria.

### Acknowledgments

We gratefully acknowledge the thoughtful comments of Dr Bertie Argyris and Dr Candice Mc-Coy, who reviewed the immunology section, and Dr Donald Heyneman, who reviewed the parasitology section. The excellent secretarial skills of Grace Stauffer and Bertha Cooke are greatly appreciated. We are indebted to the editor of the first five editions, Yvonne Strong, and to the editor of the sixth edition, Cara Lyn Coffey, both of whom ensured that the highest standards of grammar and style were met.

- W. L. gratefully acknowledges the invaluable assistance of his wife, Barbara, in making this book become a reality.
- W. L. dedicates this book to his father and mother, who instilled a love of scholarship, the joy of teaching, and the value of being organized.

## Part I: Basic Bacteriology

# Bacteria Compared With Other Microorganisms

1

#### **AGENTS**

The agents of human infectious diseases belong to five major groups of organisms: bacteria, fungi, protozoa, helminths, and viruses. The bacteria belong to the prokaryote kingdom, the fungi and protozoa are members of the kingdom of protists, and the helminths (worms) are classified in the animal kingdom (Table 1–1). The protists are distinguished from animals and plants by being either unicellular or relatively simple multicellular organisms. The helminths are complex multicellular organisms that are classified as metazoa within the animal kingdom. Taken together, the helminths and the protozoa are commonly called parasites. Viruses are quite distinct from other organisms. They are not cells but can replicate only within cells.

### **IMPORTANT FEATURES**

Many of the essential characteristics of these organisms are described in Table 1–2. One salient feature is that bacteria, fungi, protozoa, and helminths are cellular whereas viruses are not. This distinction is based primarily on three criteria.

- (1) Structure. Cells have a nucleus or nucleoid (see below) containing DNA; this is surrounded by cytoplasm, within which proteins are synthesized and energy is generated. Viruses have an inner core of genetic material (either DNA or RNA) but no cytoplasm, and so they depend on host cells to provide the machinery for protein synthesis and energy generation.
- (2) Method of replication. Cells replicate either by binary fission or by mitosis, during which one parent cell divides to make two progeny cells while retaining its cellular structure. Prokaryotic cells, eg, bacteria, replicate by binary fission, whereas eukaryotic cells replicate by mitosis. In contrast, viruses disassemble, produce many copies of their nucleic acid and protein, and then reassemble into multiple progeny viruses. Furthermore, viruses must replicate within host cells because, as mentioned above, they lack protein-synthesizing and energy-generating systems. With the exception of rickettsiae and chlamydiae, which are bacteria that also require living host cells for growth, bacteria can replicate extracellularly.

**Table 1–1.** Biologic relationships of pathogenic microorganisms.

Kingdom	Pathogenic Microorganisms	Type of Cells
Animal	Helminths	Eukaryotic
Plant	None	Eukaryotic
Protist	Protozoa Fungi	Eukaryotic Eukaryotic
Prokaryote	Bacteria	Prokaryotic
	Viruses	Noncellular

Characteristic	Viruses	Bacteria	Fungi	Protozoa and Helminths
Cells	No	Yes	Yes	Yes
Approximate diameter (μm) <sup>1</sup>	0.02-0.2	1-5	3-10 (yeasts)	15-25 (trophozoites)
Nucleic acid	Either DNA or RNA	Both DNA and RNA	Both DNA and RNA	Both DNA and RNA
Type of nucleus	None	Prokaryotic	Eukaryotic	Eukaryotic
Ribosomes	Absent	70S	80S	80S
Mitochondria	Absent	Absent	Present	Present
Nature of outer surface	Protein capsid and lipoprotein envelope	Rigid wall containing peptidoglycan	Rigid wall containing chitin	Flexible membrane
Motility	None	Some	None	Most
Method of replication	Not binary fission	Binary fission	Budding or mitosis <sup>2</sup>	Mitosis <sup>3</sup>

Table 1-2. Comparison of medically important organisms.

(3) Nature of the nucleic acid. Cells contain both DNA and RNA, whereas viruses contain either DNA or RNA but not both.

### **EUKARYOTES & PROKARYOTES**

Cells have evolved into two fundamentally different types, eukaryotic and prokaryotic, which can be distinguished on the basis of their structure and the complexity of their organization. Fungi and protozoa are eukaryotic, whereas bacteria are prokaryotic.

- (1) The eukaryotic cell has a true **nucleus** with multiple chromosomes surrounded by a nuclear membrane and uses a mitotic apparatus to ensure equal allocation of the chromosomes to progeny cells.
- (2) The **nucleoid** of a prokaryotic cell consists of a single circular molecule of loosely organized DNA lacking a nuclear membrane and mitotic apparatus (Table 1-3).

In addition to the different types of nuclei, the two classes of cells are distinguished by several other characteristics.

- (1) Eukaryotic cells contain **organelles**, such as mitochondria and lysosomes, and larger (80S) ribosomes, whereas prokaryotes contain no organelles and smaller (70S) ribosomes.
- (2) Most prokaryotes have a rigid external cell wall that contains **peptidoglycan**, a polymer of amino acids and sugars, as its unique structural component. Eukaryotes, on the other hand, do not contain

Characteristic	Prokaryotic Bacterial Cells	Eukaryotic Human Celis
DNA within a nuclear membrane	No	Yes
Mitotic division	No	Yes
DNA associated with histones	No	Yes
Chromosome number	One	More than one
Membrane-bound organelles, such as mitochondria and lysosomes	No	Yes
Size of ribosome	70S	80S
Cell wall containing peptidoglycan	Yes	No

Table 1-3. Characteristics of prokaryotic and eukaryotic cells.

<sup>&</sup>lt;sup>1</sup> For comparison, a human red blood cell has a diameter of 7 μm.

<sup>&</sup>lt;sup>2</sup> Yeasts divide by budding, whereas molds divide by mitosis.

<sup>&</sup>lt;sup>9</sup> Helminth cells divide by mitosis, but the organism reproduces itself by complex, sexual life cycles.

peptidoglycan. Either they are bound by a flexible cell membrane or, in the case of fungi, they have a rigid cell wall with chitin, a homopolymer of N-acetylglucosamine, typically forming the framework.

(3) The eukaryotic cell membrane contains sterols, whereas no prokaryote, except the wall-less Mycoplasma, has sterols in its membranes.

Motility is another characteristic by which these organisms can be distinguished. Most protozoa and some bacteria are motile, whereas fungi and viruses are nonmotile. The protozoa are a heterogeneous group that possess three different organs of locomotion: flagella, cilia, and pseudopods. The motile bacteria move only by means of flagella.

### **REVIEW QUESTIONS**

- 1. What are the differences between bacteria and viruses?
- 2. Are bacteria prokaryotic or eukaryotic? What are the differences between prokaryotic and eukaryotic cells?
- 3. What are the similarities and the differences among bacteria, fungi, and protozoa?

### **Structure of Bacterial Cells**

2

### SHAPE & SIZE

Bacteria are classified by shape into three basic groups: **cocci, bacilli,** and **spirochetes** (Figure 2-1). The cocci are round, the bacilli are rods, and the spirochetes are spiral-shaped. Some bacteria are variable in shape and are said to be **pleomorphic** (many-shaped). The shape of a bacterium is determined by its rigid cell wall. The microscopic appearance of a bacterium is one of the most important criteria used in its identification.

In addition to their characteristic shapes, the arrangement of bacteria is important. For example, certain cocci occur in pairs (diplococci), some in chains (streptococci), and others in grapelike clusters (staphylococci). These arrangements are determined by the orientation and degree of attachment of the bacteria at the time of cell division.

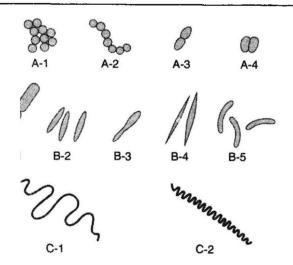

Figure 2–1. Bacterial morphology. A: Cocci: in clusters, eg, Staphylococcus (A-1); chains, eg, Streptococcus (A-2); in pairs with pointed ends, eg, Streptococcus pneumoniae (A-3); in pairs with kidney bean shape, eg, Neisseria (A-4). B: Rods (bacilli): with square ends, eg, Bacillus (B-1); with rounded ends, eg, Salmonella (B-2); club-shaped, eg, Corynebacterium (B-3); fusiform, eg, Fusobacterium (B-4); comma-shaped, eg, Vibrio (B-5). C: Spirochetes: relaxed coil, eg, Borrelia (C-1); tightly coiled, eg, Treponema (C-2). (Modified and reproduced, with permission, from Joklik WK et al: Zinsser Microbiology, 20th ed. Originally published by Appleton & Lange. Copyright © 1992 by The McGraw-Hill Companies.)

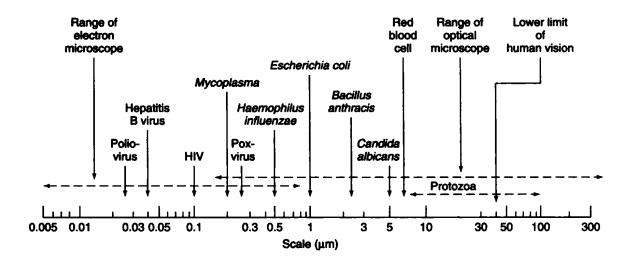

Figure 2–2. Sizes of representative bacteria, viruses, yeasts, protozoa, and human red cells. The bacteria range in size from *Mycoplasma*, the smallest, to *Bacillus anthracis*, one of the largest. The viruses range from poliovirus, one of the smallest, to poxviruses, the largest. Yeasts, such as *C albicans*, are generally larger than bacteria. Protozoa have many different forms and a broad size range. HIV = human immunodeficiency virus. (Modified and reproduced, with permission, from Joklik WK et al: *Zinsser Microbiology*, 20th ed. Originally published by Appleton & Lange. Copyright © 1992 by The McGraw-Hill Companies, Inc.)

Bacteria range in size from about 0.2 to 5  $\mu$ m (Figure 2-2). The smallest bacteria (*Mycoplasma*) are about the same size as the largest viruses (poxviruses) and are the smallest organisms capable of existing outside a host. The longest bacteria rods approach the size of some yeasts and human red blood cells (7  $\mu$ m).

### **STRUCTURE**

The structure of a typical bacterium is illustrated in Figure 2-3, and the important features of each component are presented in Table 2-1.

**Cell Wall** The cell wall is the outermost component common to all bacteria (except *Mycoplasma* species, which are bounded by a cell membrane, not a cell wall). Some bacteria have surface features external to the cell wall, such as a capsule, flagella, and pili, which are less common components and are discussed below.

The cell wall is a multilayered structure located external to the cytoplasmic membrane. It is composed of an inner layer of **peptidoglycan** (see p 5) and an outer membrane that varies in thickness and chemical composition depending upon the bacterial type (Figure 2-4). The peptidoglycan provides structural support and maintains the characteristic shape of the cell.

- **A.** Cell Walls of Gram-Positive and Gram-Negative Bacteria: The structure, chemical composition, and thickness of the cell wall differ in gram-positive and gram-negative bacteria (Table 2–2 and Box).
- (1) The peptidoglycan layer is much thicker in gram-positive than in gram-negative bacteria. Some gram-positive bacteria also have fibers of teichoic acid that protrude outside the peptidoglycan, whereas gram-negative bacteria do not.
- (2) In contrast, the gram-negative organisms have a complex outer layer consisting of lipopolysaccharide, lipoprotein, and phospholipid. Lying between the outer-membrane layer and the cytoplasmic membrane in gram-negative bacteria is the **periplasmic space**, which is the site, in some species, of enzymes called  $\beta$ -lactamases that degrade penicillins and other  $\beta$ -lactam drugs.

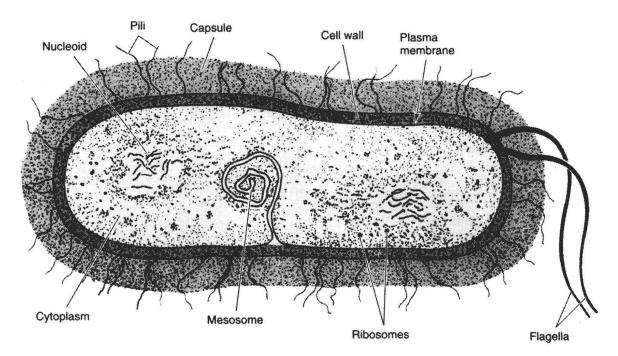

Figure 2-3. Bacterial structure. (Modified and reproduced, with permission, from Tortora G, Funk B, Case C: *Microbiology: An Introduction*, 5th ed. Benjamin/Cummings, 1995.)

The cell wall has several other important properties:

- (1) In gram-negative organisms, it contains **endotoxin**, a lipopolysaccharide (see pp 6 and 38).
- (2) Its polysaccharides and proteins are antigens that are useful in laboratory identification.
- (3) Its **porin** proteins play a role in regulating the passage of small, hydrophilic molecules into the cell. Porin proteins in the outer membrane form a trimer that acts, usually nonspecifically, as a channel to allow the entry of essential substances such as sugars, amino acids, vitamins, and metals, as well as many antimicrobial drugs such as penicillins.
- **B.** Cell Walls of Acid-Fast Bacteria: Mycobacteria, eg, Mycobacterium tuberculosis, have an unusual cell wall, resulting in their inability to be Gram-stained. These bacteria are said to be acid-fast, because they resist decolorization with acid-alcohol after being stained with carbolfuchsin. This property is related to the high concentration in the cell wall of lipids called mycolic acids.

In view of their importance, three components of the cell wall, ie, peptidoglycan, lipopolysaccharide, and teichoic acid, will be discussed in detail.

**C. Peptidoglycan:** Peptidoglycan is a complex, interwoven network that surrounds the entire cell and is composed of a single covalently linked macromolecule. It is found only in bacterial cell walls. It provides rigid support for the cell, is important in maintaining the characteristic shape of the cell, and allows the cell to withstand media of low osmotic pressure, such as water. A representative segment of the peptidoglycan layer is shown in Figure 2–5. The term "peptidoglycan" is derived from the peptides and the sugars (glycan) that make up the molecule. Synonyms for peptidoglycan are murein and mucopeptide.

Figure 2-5 illustrates the carbohydrate backbone, which is composed of alternating N-acetylmuramic acid and N-acetylglucosamine molecules. Attached to each of the muramic acid molecules is a tetrapeptide consisting of both D- and L-amino acids, the precise composition of which differs from one bacterium to another. Two of these amino acids are worthy of special mention: diaminopimelic acid, which is unique to bacterial cell walls, and D-alanine, which is involved in the cross-links between the tetrapeptides and in the action of penicillin. Note that this tetrapeptide contains the rare D-isomers of amino acids; most proteins contain the L-isomer. The other important component in this

Table 2-1. Bacterial structures.

Structure	Chemical Composition	Function
Essential components Cell wall		
Peptidoglycan	Sugar backbone with peptide side chains that are crosslinked	Gives rigid support, protects against osmotic pressure; is the site of action of penicillins and cephalosporins and is degraded by lysozyme.
Surface fibers of gram- positive bacteria	Teichoic acid	Major surface antigen but rarely used in laboratory diagnosis.
Outer membrane of gram- negative bacteria	Lipid A	Toxic component of endotoxin.
	Polysaccharide	Major surface antigen used frequently in laboratory diagnosis.
Cytoplasmic membrane	Lipoprotein bilayer without sterols	Site of oxidative and transport enzymes.
Ribosome	RNA and protein in 50S and 30S subunits	Protein synthesis; site of action of aminoglycosides, erythromycin, tetracyclines, and chloramphenicol.
Nucleoid	DNA	Genetic material.
Mesosome	Invagination of plasma membrane	Participates in cell division and secretion.
Periplasm	Space between plasma membrane and outer membrane	Contains many hydrolytic enzymes, including β-lactamases.
Nonessential components Capsule	Polysaccharide <sup>1</sup>	Protects against phagocytosis.
Pilus or fimbria	Glycoprotein	Two types: (1) mediates attachment to cell surfaces; (2) sex pilus mediates attachment of two bacteria during conjugation.
Flagellum	Protein	Motility.
Spore	Keratinlike coat, dipicolinic acid	Provides resistance to dehydration, heat, and chemicals.
Plasmid	DNA	Contains a variety of genes for antibiotic resistance and toxins.
Granule	Glycogen, lipids, polyphosphates	Site of nutrients in cytoplasm.
Glycocalyx	Polysaccharide	Mediates adherence to surfaces.

<sup>&</sup>lt;sup>1</sup>Except in Bacillus anthracis, in which it is a polypeptide of p-glutamic acid.

network is the peptide cross-link between the two tetrapeptides. The cross-links vary among species; in *Staphylococcus aureus*, for example, five glycines link the terminal D-alanine to the penultimate L-lysine.

Because peptidoglycan is present in bacteria but not in human cells, it is a good target for antibacterial drugs. Several of these drugs, such as the penicillins and cephalosporins, inhibit its synthesis by inhibiting the transpeptidase that makes the cross-links between the two adjacent tetrapeptides (see Chapter 10).

The enzyme **lysozyme**, which is present in human tears, mucus, and saliva, can cleave the peptidoglycan backbone by breaking its glycosyl bonds, thereby contributing to the natural resistance of the host to microbial infection. Lysozyme-treated bacteria may swell and rupture as a result of the entry of water into the cells, which have a high internal osmotic pressure. However, if the lysozyme-treated cells are in a solution with the same osmotic pressure as that of the bacterial interior, they will survive as spherical forms, called protoplasts, surrounded only by a cytoplasmic membrane.

**D.** Lipopolysaccharide (LPS): The LPS of the outer membrane of the cell wall of gram-negative bacteria is endotoxin. It is responsible for many of the features of disease, such as fever and shock (especially hypotension), caused by these organisms. It is called endotoxin because it is an integral part of the cell wall, in contrast to exotoxins, which are freely released from the bacteria. The pathologic effects of endotoxin are similar irrespective of the organism from which it is derived.

The LPS is composed of three distinct units (Figure 2–6):

(1) A phospholipid called lipid A, which is responsible for the toxic effects

Figure 2–4. Cell walls of gram-positive and gram-negative bacteria. Note that the peptidoglycan in gram-positive bacteria is much thicker than in gram-negative bacteria. Note also that only gram-negative bacteria have an outer membrane containing endotoxin (lipopolysaccharide [LPS]) and have a periplasmic space where β-lactamases are found. Several important gram-positive bacteria, such as staphylococci and streptococci, have teichoic acids. (Reproduced, with permission, from Ingraham JL, Maaløe O, Neidhardt FC: *Growth of the Bacterial Cell*. Sinauer Associates, 1983.)

- (2) A core polysaccharide of five sugars linked through ketodeoxyoctulonate (KDO) to lipid A
- (3) An outer polysaccharide consisting of up to 25 repeating units of three to five sugars. This outer polymer is the important somatic, or O, antigen of several gram-negative bacteria that is used to identify certain organisms in the clinical laboratory.
- **E. Teichoic Acid:** These polymers of glycerol phosphate or ribitol phosphate are located in the outer layer of the gram-positive cell wall. Some polymers of glycerol teichoic acid penetrate the peptidoglycan layer and are covalently linked to the lipid in the cytoplasmic membrane, in which case they are called **lipoteichoic acid;** others anchor to the muramic acid of the peptidoglycan. Teichoic acids are antigenic and induce antibodies that are species-specific. In staphylococci, teichoic acids mediate adherence of the organism to mucosal cells.

**Cytoplasmic Membrane** Just inside the peptidoglycan layer of the cell wall lies the cytoplasmic membrane, which is composed of a phospholipid bilayer similar in microscopic appearance to that in eukaryotic cells. They are chemically similar, but eukaryotic membranes contain sterols, whereas prokaryotes generally do not. The only prokaryotes that have sterols in their membranes are members of the genus *Mycoplasma*. The membrane has four important functions: (1) active transport of molecules into the cell, (2) energy generation by oxidative phosphorylation, (3) synthesis of precursors of the cell wall, and (4) secretion of enzymes and toxins.

**Mesosome** This invagination of the cytoplasmic membrane is important during cell division, when it functions as the origin of the transverse septum that divides the cell in half and as the binding site of the DNA that will become the genetic material of each daughter cell.

**Table 2–2.** Comparison of cell walls of gram-positive and gram-negative bacteria.

Component	Gram-Positive Cells	<b>Gram-Negative Cells</b>	
Peptidoglycan	Thicker; multilayer	Thinner; single layer	
Teichoic acids	Yes	No	
Lipopolysaccharide (endotoxin)	No	Yes	

#### **Gram Stain**

This staining procedure, developed in 1884 by the Danish physician Christian Gram, is the most important procedure in microbiology. It separates most bacteria into two groups: the gram-positive bacteria, which stain blue, and the gram-negative bacteria, which stain red. The Gram stain involves the following four-step procedure.

- (1) The crystal violet dye stains all cells blue.
- (2) The iodine solution (a mordant) is added to form a crystal violet-iodine complex; all cells continue to appear blue.
- (3) The organic solvent, such as acetone or ethanol, extracts the blue dye complex from the lipid-rich, thin-walled gram-negative bacteria to a greater degree than from the lipid-poor, thick-walled gram-positive bacteria. The gram-negative organisms appear colorless; the gram-positive bacteria remain blue.
- (4) The red dye safranin stains the decolorized gram-negative cells red; the gram-positive bacteria remain blue.

Note that if step #2 is omitted and Gram's iodine is not added, gram-negative bacteria stain *blue* rather than pink, presumably because the organic solvent removes the crystal violet-iodine complex but not the crystal violet alone. Gram-positive bacteria also stain *blue* when Gram's iodine is not added.

The Gram stain is useful in two ways:

- (1) In the identification of many bacteria
- (2) In influencing the choice of antibiotic, because, in general, gram-positive bacteria are more susceptible to penicillin G than are gram-negative bacteria.

However, not all bacteria can be seen in the Gram stain. Table 2-3 lists the medically important bacteria that cannot be seen and describes the reason why. The alternative microscopic approach to the Gram stain is also described.

**Cytoplasm** The cytoplasm has two distinct areas when seen in the electron microscope:

- (1) An amorphous matrix that contains ribosomes, nutrient granules, metabolites, and plasmids
- (2) An inner, nucleoid region composed of DNA.
- A. Ribosomes: Bacterial ribosomes are the site of protein synthesis as in eukaryotic cells, but they differ from eukaryotic ribosomes in size and chemical composition. Bacterial ribosomes are

Table 2-3. Medically important bacteria that cannot be seen in the Gram stain.

	Name	Reason	Alternative Microscopic Approach	
	Mycobacteria, including M tuberculosis	Too much lipid in cell wall	Acid-fast stain	
	Treponema pallidum	Too thin to see	Dark-field microscopy or fluorescent antibody	
	Mycoplasma pneumoniae	No cell wall; very small	None	
	Legionella pneumoniae	Poor uptake of red counterstain	Prolong time of counterstain	
	Chlamydiae, including C trachomatis	Intracellular; very small	Inclusion bodies in cytoplasm	
.11. 11 1 101-	Rickettsiae	Intracellular; very small	Giemsa or other tissue stains
