## Principal Mathematical Symbols Used in This Work

For a general quantity  $M$ , the subscripts and superscripts denote the following associations:

$M_i, M_j$	with the $i$ -th and the $j$ -th particle, respectively
$M_n$	with the $n$ -th quantum state
$M_E$	with the electric field
$M_H$	with the magnetic field
$M_K$	with a generalized field $K$ (for $E$ or $H$ )
$M_e$	with an electric reaction
$M_m$	with a magnetic reaction
$M_D$	with the dipole moment
$M_Q$	with the quadrupole moment
$M_O$	with the octopole moment
$M^l$	with the linear process
$M^s$	with the nonlinear phase-sensitive process
$M^i$	with the nonlinear phase-insensitive process
$M_b$	with a backward wave
$M_f$	with a forward wave
$M_\nu, M(\omega_\nu)$	with the frequency of $\omega_\nu$

Other denotations and designations are:

$M_s, M_o$	= a static quantity
$M_d$	= a dynamic quantity
$M^o$	= an unperturbed quantity
$M^{(\nu)}$	= $\vec{M} \cdot \vec{e}_\nu$ = the scalar product of $\vec{M}$ and the unit vector $\vec{e}_\nu$
$M^{[\mu]}$	= $M$ in individual steps of expansion
$M$	= $M' - iM''$ = real and imaginary parts of $M$
$ M $	= magnitude
$\vec{M}$	= vector
$  M_{kl}  $	= matrix
$[M_{ij}]$	= tensor of second rank
$[M_{ijk}]$	= tensor of third rank
$ M\rangle$	= ket $M$
$\langle M $	= bra $M$
$\langle M \rangle$	= expectation value of $M$ .

The multitude of the most variegated quantities required for the presentation made it mandatory that a given symbol had to be reused for various quantities. In so doing, great attention was paid, however, to ensure that such quantities appear in separate fields so that confusion should be virtually impossible.

$A$	= vector potential, amplitude function, field constant of a reflected wave in a multilayer structure
$A_n, A_\mu$	= normalization constants
$a$	= power series coefficient of a potential function
$B$	= magnetic flux density, field constant of a transmitted wave in a multilayer structure
$b$	= see $a$
$C$	= general field constant
$c$	= velocity of light in the vacuum
$D$	= dielectric displacement
$d$	= damping constant
$E$	= energy, electric field strength
$e$	= unit vector
$F$	= force
$f$	= distribution function
$g$	= gyromagnetic ratio, complex frequency response
$H$	= Hamiltonian, magnetic field strength
$h$	= Planck's constant ( $h = h/2\pi$ )
$i$	= imaginary unit
$K$	= generalized field symbol (for $E$ or $H$ )
$k$	= Boltzmann's constant, propagation coefficient
$L$	= length
$l$	= orbital angular momentum
$m$	= particle mass
$N$	= number of particles per unit volume
$n$	= normal vector
$P$	= power per unit volume
$p$	= momentum
$p_{pq}$	= induced transition probabilities between states $p$ and $q$
$q$	= particle charge
$R$	= radius in the macroscopic $R$ -space

Principal Mathematical Symbols Used in This Work

$r$	= radius in the microscopic $r$ -space
$r^a, r^b$	= reflection coefficients at the boundaries $a$ and $b$ , respectively
$s$	= spin angular momentum
$T$	= absolute temperature
$T_{pq}$	= relaxation constants between states $p$ and $q$
$t$	= time
$t_{pq}$	= thermal transition probabilities between states $p$ and $q$
$V$	= potential energy
$v$	= velocity of light in the substance
$W$	= perturbation energy
$x$	= damping reduction factor
$\alpha$	= coefficient of characteristic curves, friction coefficient (loss correction)
$\beta$	= propagation coefficient
$\beta_0$	= Bohr magneton
$\Gamma$	= propagation coefficient
$\gamma$	= generalized dimensional moment parameter ( $\pi = \gamma\xi$ )
$\Delta E$	= unperturbed energy difference
$\Delta k$	= phase mismatch
$\Delta \omega$	= bandwidth (angular frequency -)
$\delta$	= transmissivity coefficient
$\delta_{pq}$	= Kronecker - $\delta$
$\epsilon$	= relative permittivity
$\epsilon_0$	= vacuum permittivity
$\eta$	= generalized symbol for $\epsilon$ or $\mu$
$\eta_0$	= generalized symbol for $\epsilon_0$ or $\mu_0$
$\kappa$	= propagation coefficient
$\lambda$	= wavelength, ordering parameter with perturbation calculations
$\mu$	= relative permeability
$\mu_0$	= vacuum permeability
$\nu$	= frequency
$\xi$	= generalized dimensionless moment parameter ( $\pi = \gamma\xi$ )
$\Pi$	= polarization
$\pi$	= moment
$\rho$	= density operator
$\varphi$	= scalar potential, phase angle
$\chi$	= susceptibility
$\psi$	= wave function, state vector
$\omega$	= angular frequency

## Some Universal Constants (SI-units)

$$\epsilon_0 = 8.855 \times 10^{-14} \text{ AsV}^{-1} \text{ cm}^{-1}$$

$$\mu_0 = 1.257 \times 10^{-8} \text{ VsA}^{-1} \text{ cm}^{-1}$$

$$q_0 = -1.602 \times 10^{-19} \text{ As}$$

$$m_0 = 9.108 \times 10^{-28} \text{ g} = 9.108 \times 10^{-35} \text{ VAs}^3 \text{ cm}^{-2}$$

$$\hbar = \hbar/2\pi = 1.054 \times 10^{-34} \text{ VAs}^2$$

$$g_0 = \frac{\mu_0 q_0}{m_0} = -2.211 \times 10^7 \text{ cmA}^{-1} \text{ s}^{-1} \text{ (spin)}$$

$$\beta_0 = \frac{\mu_0 q_0 \hbar}{2m_0} = -1.165 \times 10^{-27} \text{ Vscm}$$

$$k = 1.380 \times 10^{-23} \text{ VAsK}^{-1}$$

$$c = 3 \times 10^{10} \text{ cms}^{-1} \text{ (more exactly: } c = 2.998 \times 10^{10} \text{ cms}^{-1}\text{)}$$

$$\frac{q_0}{m_0} = -1.759 \times 10^8 \text{ Asg}^{-1} = -1.759 \times 10^{15} \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-2}$$

$$\frac{\beta_0}{\hbar} = -1.105 \times 10^7 \text{ cmA}^{-1} \text{ s}^{-1}$$

$$kT_0 = 4.043 \times 10^{-21} \text{ VAs}$$

$$T_0 = 293 \text{ K}$$

$$\frac{\hbar}{kT_0} = 1.638 \times 10^{-13} \text{ s}$$

## Preface

This book was written by an engineer. The author's interest centered, and still centers, on all the principles and methods by means of which, in their specific application to the techniques employed at radio and light frequencies and specifically in communications, electromagnetic fields can be produced or amplified from very low levels, as well as on principles that can be used for modulation, rectification, etc.

All these effects are based on interactions between electromagnetic fields and matter. In the absence of matter, the linear laws of the vacuum field apply — except in the case of extreme high-energy problems —: the field exists, but no additional effects appear.

The laws of classical physics suffice in most cases for a description of the various interaction phenomena. This also applies to interactions that, strictly speaking, are based on typical mechanisms of quantum mechanics: provided matter is held concentrated generally in an  $n$ -pole structural element (diodes, transistors, tunnel-elements, etc.) there is no absolute need for the engineer or physicist to care about what may happen inside these elements. Knowledge concerning the combined effect of the individual parameters as derived from a single measurement at the terminals suffices for their purposeful application.

When, however, matter is used as an extended medium, and when the related frequencies become so high that a quasistatic analysis is no longer possible, or when, quite generally, the mechanisms of the interactions are to be covered in greater detail, one must resort for a description to the theory where matter is on its own — quantum theory.

It was here in particular that the discovery of the maser <sup>1)</sup> principle, corresponding to the first aspect mentioned above, also induced the engineer to deal more thoroughly with the interaction phenomena, beyond a purely phenomenological line of thought. The application of this concept to the infrared and visible ranges of the spectrum later on led to the generation of coherent waves at these frequencies for the first time (laser <sup>2)</sup>), whilst use of the laser as a source of excitation simultaneously opened up the possibility of realizing at these frequencies the multitude of nonlinear interaction processes familiar from the classical range.

If the analysis of the interaction phenomena is restricted to the complex with energy-storing matter — as will be done throughout this book — the processes known from classical concepts in conjunction with concentrated components are nonlinear processes, for they are the ones that are of essential practical importance. In the extended medium, however, with the lack of frequency-limiting elements such as package capacitances and lead inductances, further processes of interest develop. The frequencies of the process fields now can reach coincidence with the natural resonances of matter itself. This lends practical import also to the linear interaction process while simultaneously the wide spectrum of nonlinear processes is enriched by additional variants.

This book has as its goal a presentation as comprehensive as possible of the mechanisms of the most variegated processes. Their discussion, firstly not closely associated with any practical problems, should here be useful not only to the engineer, but to every natural scientist. It is hoped at least, although, in particular the quantum-mechanical treatment of the various phenomena has been derived from the mentality of an engineer.

The book has six chapters. The first two give an introduction and survey with the means of classical mechanics. In particular the first chapter begins, by considering, firstly, a cluster of charged mass points in the external field, with a determination of the quantities that decisively control the interaction pattern between fields and matter. The chapter terminates with a derivation and interpretation of the individual electric and magnetic moments. The second chapter continues with classical introductions. The picture of matter is subjected to advanced development by dealing with some elementary microscopic models such as the central-field model and the oscillator model. The typical electric and magnetic characteristic curves are derived for the individual models. These relationships already allow many conclusions to be made concerning the interaction pattern with electromagnetic fields. With a general macroscopic characteristic curve a survey is subsequently given of the entire multitude of the various processes. The presentation covers the principal interaction effects up to, and including, the cubic processes. A reader who wants to begin by obtaining a general survey should start here. The systematic treatment of the subject matter made it apparent that it would not be advisable to place this part at the beginning of the book.

---

<sup>1)</sup> Microwave Amplification by Stimulated Emission of Radiation

<sup>2)</sup> Light Amplification by Stimulated Emission of Radiation

The third chapter introduces the nonclassical part. As a first step the principal fundamentals of quantum mechanics are sketched to the extent required for the set of topics that are of interest. Considerable room has been devoted to the various representation methods of the perturbed particle system — methods that allow the interactions between fields and matter to be covered. Following a general discussion of the methods a specific method finally is chosen that is adapted to the scope of this book in its entirety. Its specialization to the problems of interest is the starting point for the further specialized analysis, while simultaneously terminating this third chapter.

Chapters four and five discuss special interaction processes. The fourth chapter is here closely related in particular with the second chapter, because a general static characteristic curve of matter is here determined, now indeed in terms of the formalism of quantum mechanics. Here, as well as there, all static and quasistatic processes can be easily described, processes whose frequencies are far away from any eigenresonances of matter. It is, in particular, these considerations which establish a direct link with the original classical methods. Whilst including them they give them a more profound interpretation at the same time.

Chapter five deals with the principal resonance processes. At least one of the process frequencies here coincides with a natural resonance of matter. The presentation covers interactions via the linear resonance process (maser, laser), typical interactions via nonlinear resonance processes (multi-quantum absorption and emission, respectively, Raman processes), but also processes such as frequency multiplication, frequency division, parametric mixing processes etc., processes that otherwise take place away from the resonance ranges as a rule. Chapter five ends with an attempt to give an interpretation concerning common traits of the various types of processes.

In the sixth and last chapter the studies of the microscopic reactions are followed by a discussion of a few selected processes concerning their behavior in macroscopic structures. The theoretical analysis here reverts again to the classical presentation: the relationships gained from quantum-mechanical investigations are linked with Maxwell's theory. Specializations allow reactions in microwave structures as well as in structures for optical frequencies to be obtained from the so found relationships. A presentation in a way as uniform and fundamental as possible cannot, however, take into account the most varying forms of macroscopic structures, but must confine itself to a single fundamental and straightforward one. The essential properties in macroscopic structures are so outlined uniformly for all processes under discussion.

The six chapters of the book are followed by an appendix that further illustrates the general relationships by reference to two elementary models of matter. The electron spin has been chosen for this purpose as a basic example of magnetic interactions in the microwave range, as well as the anharmonic oscillator which is to be representative of the hydrogen molecule. It gives a basic example of typical interactions in the range of the infrared spectrum.

The bibliography is compiled as a unit at the end of the book. It includes the literature related to the subject matter, but no general fundamental literature. The latter is quoted

in footnotes in the individual chapters. The classical complex of interactions is covered in the collection merely in its mile-stones, and the reader is referred to books that already are of a synoptical character. More detailed attention has been paid to the nonclassical complex. In conjunction with a survey of the historical evolution, it is in particular the experimental work that should be highlighted to some extent because there is no room available for this in a purely theoretical presentation such as this book is.

The brief survey concerning the contents of the book, with the concept of a 'characteristic curve' of a structural element and its adoption to a system of matter already reveals an engineers mentality. The mixing of the line of thought of physicists and engineers goes on throughout the book. Such mixed presentation will indeed cause some confusion to one of the parties while it should aid simultaneously in opening up an access road to the other party. This problematic situation will come about whenever originally separated disciplines meet at a joint frontier.

The scope of the problems touched, starting as it did, from a cluster of charged mass points in the external field up to the macroscopic structures of a frequency doubler or a Raman laser as examples demanded concessions to be made in the presentation. A systematic course, without excessive encumbrance, had to be taken in a way that was as short as possible. In particular in the classical part, this even gave rise to a few modifications of the theory which, however, will be justified when one keeps the entire scope of the book in mind.

Presentation and derivation of the individual processes were, however, made in great detail. A reader merely interested in the final results may, of course, skip over the intermediate steps. Attention to detail is appropriate and necessary whenever general physical results become the object of an engineer's work. This also explains the large number of specializations of the general relationships, last but not least in order to establish from the special examples links between quantum-mechanical results and familiar classical concepts. The international system of units is used throughout the book with freely selectable orders of magnitude of the basic units.

It is with great pleasure that I express my gratitude to the few who have assisted me with advice and encouragement in the writing of this book. In particular, I desire to thank Dr.-Ing. habil. W. Kautter, Munich, as the translator, Prof. Dr. H. G. Andresen, Mainz, for discussions on certain problems, and Prof. Dr. H. Stumpf, Tübingen, as editor and critic. My gratitude is likewise due to Dr. G. Schollmeier, Munich, and G. R. Jones, M. Sc., London, for help in reading the manuscript.

It is my sincere hope that the book will help all those who wish to make a detailed study of the problems treated.

## Contents

Principal Mathematical Symbols Used in This Work	V
Some Universal Constants (SI-units)	XIII

### Introductory Remarks 1

1. Storing Matter and Dissipating Matter	1
2. Some Phenomenological Considerations to the Reactions of Matter	2

## I Matter as a Conglomeration of Charged Mass Points in the Electromagnetic Field

1. The Hamiltonian of Charged Particles in the External Field	7
2. Analysis of the Hamiltonian	9
2.1. Field Analysis	10
2.2. The Interaction Terms	12
3. Multipole Moments	15
3.1. Dipole, Quadrupole, Octopole Moments	16
3.2. Permanent and Induced Moments	18
3.3. Tentative Illustrative and Conceptual Interpretation of the Individual Moments	19

## II Microscopic Models, Characteristic Curves, Processes

1. Models of Matter	22
2. The Equation of Motion of Charged Particles in the Electromagnetic Field	24
2.1. Derivation from the Hamiltonian	24
2.2. Equation of Motion with Purely Electric Fields	25
2.3. Equation of Motion with Purely Magnetic Fields	26
2.3.1. The Larmor-Bloch Equation	27
2.3.2. Modification of the Larmor-Bloch Equation	29
3. Characteristic Curves	31
3.1. Electric Characteristic Curves	31
3.1.1. Dipole Characteristics	31
3.1.1.1. Oscillator Types	31
3.1.1.2. Central-field Types	35
3.1.2. The Quadrupole Characteristic Curve in a Linear System of Matter	38
3.2. Magnetic Characteristic Curves	39
3.2.1. Dipole Characteristics	39
3.2.2. Remarks Concerning Quadrupole Characteristics	41
3.3. The Derivatives of the Characteristic Curves, Their Frequency Dependence	41
3.4. Comparison with Well-known and Proven Storage Characteristics; Microscopic and Quasimacroscopic Bonds	45
4. Survey of the Interaction Processes	46
4.1. The Calculation of the Mixing	46
4.2. The Processes	49
4.2.1. Linear Processes	49
4.2.2. Quadratic Processes	50
4.2.3. Cubic Processes	55
5. Transition to the Discussion in Terms of Quantum Mechanics	61
5.1. Transfer, with the Help of the Correspondence Principle, of Fourier Coefficients into Matrix Elements	62
5.2. Conclusions from the Matrices	65

## III The Quantum-mechanical Treatment of the Interactions

1. The General Solution Scheme	68
1.1. The expectation Values as Theoretical Predictions of Observable Quantities	68

**XIV****Contents**

1.1.1.	Expectation Values, State Vectors, Operators	68
1.1.2.	The Description of the State	71
1.2.	Determination of the Expectation Values	72
1.2.1.	The Unperturbed Particle System	72
1.2.1.1.	Considerations with the Temporal Variation Neglected	72
1.2.1.2.	The Temporal Variation	76
1.2.2.	Types of Representation	78
1.2.2.1.	Representations of State Vectors, Operators, Expectation Values	78
1.2.2.2.	Transformations	81
1.2.3.	The Perturbed Particle System	83
1.2.3.1.	Perturbed State Vectors and Expectation Values	83
1.2.3.2.	Formulation with Density Matrices	88
1.2.3.3.	Summary and Comparison of the Results	90
2.	Special Steady-state Formulations	95
2.1.	The Perturbed Hamiltonian	95
2.1.1.	Derivation from the Classical Hamiltonian	95
2.1.2.	The Operator of the Perturbation Energy and the Operators of the Moments	96
2.1.3.	The Dynamics of the Perturbation Operator	100
2.2.	Steady-state Expectation Values	102

**IV Special Processes I: Static and Quasistatic (off-resonance) Interactions**

1.	The Static Expansion Coefficients	106
1.1.	General Considerations Concerning the Solution of the Set of Equations of the Static Expansion Coefficients	106
1.1.1.	Nondegenerate and Degenerate States	107
1.1.2.	Expansion Coefficients of a Two-state System	109
1.1.2.1.	Exact Solution for Nondegenerate and Degenerate States	109
1.1.2.2.	Approximate Solution for Nondegenerate States	113
1.2.	Determination of the General Expansion Coefficients	117
2.	The Static Characteristic Curve	118
2.1.	The Single-field Characteristic Curve and Its Special Form in a Two-state System	118
2.2.	Generalizations and Specializations	125
2.2.1.	The Characteristic Curve with a Number of Single Fields	125
2.2.1.1.	The Two-field Characteristic Curve as a Typical Multifield Characteristic	125
2.2.1.2.	The Tensor Representation	127
2.2.2.	The Quadrupole Characteristic	132
2.3.	Some Interaction Processes	135
3.	Considerations Concerning the Operating Point of Matter	137

**V Special Processes II: Dynamic Processes, in Particular Resonance Processes**

1.	Single-field Processes	141
1.1.	The Expansion Coefficients and Expectation Values of the Moments	141
1.2.	Linear Processes	143
1.2.1.	Moments and Polarizations	144
1.2.2.	The Linear Process between Two Energy States	144
1.2.2.1.	Polarization and Susceptibility	144
1.2.2.2.	The Power Conversion	148
1.3.	Nonlinear Single-field Processes	158
1.3.1.	Single-field Rectifying Effects	158
1.3.2.	Stimulated Single-field Multiquantum Processes (Transition Processes)	161
1.3.2.1.	Two-quantum Processes	162
1.3.2.2.	Three-quantum Processes	164
1.3.2.3.	Stimulated Single-field Processes for the Generation of Electromagnetic Fields	166
2.	Multifield Processes	167
2.1.	Controllable Processes	167

2.2.	Harmonic Processes	170
2.2.1.	The Second Harmonic	170
2.2.1.1.	Expansion Coefficients	170
2.2.1.2.	The Resonance Moments	171
2.2.2.	The Third Harmonic	174
2.2.2.1.	Expansion Coefficients	174
2.2.2.2.	The Resonance Moments	175
2.2.3.	Special Resonance Polarizations of Harmonic Processes	178
2.2.3.1.	The Resonant Frequency Doubling	179
2.2.3.2.	The Resonant Frequency Tripling	180
2.3.	Mixing Processes	181
2.3.1.	Expansion Coefficients and Expectation Values of the Moments in General	182
2.3.2.	The Resonance Moments of Special Mixing Processes	185
2.3.2.1.	Phase-sensitive Mixing Processes	185
2.3.2.2.	Phase-insensitive Mixing Processes	188
2.3.3.	Special Resonance Polarizations	193
3.	Power Relations of Nonlinear Resonance Processes	197
3.1.	The Process Power Values with Resonant Frequency Doubling and Mixing	197
3.1.1.	The Process Power Values in Frequency Doubling	197
3.1.1.1.	The Power Conversion in the Phase-sensitive Process	197
3.1.1.2.	The Power Conversion in the Related Phase-insensitive Process, the Overall Power Balance	202
3.1.2.	The Process Power Values in Frequency Mixing	203
3.1.2.1.	The Power Conversion in the Phase-sensitive Process at the Lower Side Frequency	203
3.1.2.2.	The Power Conversion in the Phase-insensitive Process at the Lower Side Frequency, the Overall Power Balance	206
3.1.2.3.	The Power Conversion in Mixing Processes at the Upper Side Frequency	206
3.1.3.	Comments on the Results	207
3.2.	General Power Relations of Phase-insensitive Resonance Processes and Determination of Their Transition Probabilities by Way of Phase-sensitive Interactions	208
3.2.1.	The Interpretation of the Phase-insensitive Resonance Processes by Phase-sensitive Interactions	208
3.2.2.	The Power Relations and Transition Probabilities	209
3.2.3.	Some Examples	211
4.	On the Presentation of the Resonance Processes	215

## VI Macroscopic Structures

1.	The Generalized Field Equation	218
2.	Structures with Reactions due to the Linear Process	221
2.1.	The Solution of the Elementary Case	221
2.1.1.	The Plane Wave without Aperture Limitations	221
2.1.2.	Wave Propagation in the Absence of Boundary Effects	222
2.1.3.	Wave Propagation in the Presence of Boundary Effects	223
2.1.3.1.	General Description of the Three-layer Structure	223
2.1.3.2.	Amplifiers and Oscillators	230
2.2.	The Solution with Consideration of the Tensor Properties of the Susceptibility	236
2.2.1.	The Simplest Solution	236
2.2.2.	A Special Case	238
3.	Structures with Reactions via Nonlinear Single-field Processes	242
3.1.	The Field Equation	242
3.2.	The Solution	242
3.3.	Discussion of the Solution	244
3.3.1.	Self-focusing Effects	244

3.3.2.	Amplification and Oscillation via Two-quantum Transition Processes	245
4.	Frequency Doubling in Macroscopic Structures	248
4.1.	The Field Equations	248
4.2.	The Solution	249
4.2.1.	The Solution in General and its One-dimensional Specialization	249
4.2.2.	Wave Propagation in the Absence of Boundary Effects	252
4.2.3.	Wave Propagation in the Presence of Boundary Effects	255
4.2.3.1.	The Three-layer Structure and Surface Effects	255
4.2.3.2.	The Reflection Type of the Doubler as an Example	258
5.	Frequency Mixing in Macroscopic Structures	261
5.1.	The Field Equations	261
5.2.	The Solution	263
5.2.1.	The General Solution and a Few Special Cases	263
5.2.2.	Wave Propagation in the Absence of Boundary Effects	269
5.2.2.1.	Loss-free Media	270
5.2.2.2.	Lossy Media	273
5.2.3.	Wave Propagation in the Presence of Boundary Effects	278
5.2.3.1.	The Three-layer Structure	278
5.2.3.2.	Amplifier Arrangements	281
5.3.	Comparison of the Amplification Principles	287

## Appendix

1.	The Anharmonic Oscillator as an Example of Electric Dipole Interactions in the Range of Infrared Frequencies	292
1.1.	The Parameters	292
1.1.1.	The Parameters of the Harmonic Oscillator	292
1.1.2.	The Parameters of the Anharmonic Oscillator	293
1.2.	Some Interaction Processes	296
1.2.1.	The Characteristic Curves of the Oscillator Models	296
1.2.1.1.	The Characteristic Curve of the Harmonic Oscillator	297
1.2.1.2.	The Characteristic Curve of the Anharmonic Oscillator	297
1.2.2.	Processes in Numerical Values	298
1.2.2.1.	The Adaptation of the Data	298
1.2.2.2.	The Hydrogen Characteristic Curve	300
1.2.2.3.	Frequency Doubling in Hydrogen	300
2.	The Single Spin as an Example of Magnetic Dipole Interactions in the Microwave Range	302
2.1.	The Parameters	302
2.1.1.	The Parameters in the Presence of Degeneracy	302
2.1.2.	The Parameters with Cancellation of the Degeneracy	303
2.1.3.	The Parameters with Cancellation of the Degeneracy and an Additional Field $H_0 \rightarrow$	303
2.2.	Some Interaction Processes	305
2.2.1.	The Spin Characteristic Curve	306
2.2.2.	Comparison of Static and Dynamic Spin Tensors	307
2.2.3.	Orientation Dependence of Individual Processes	310
2.2.4.	Processes in Numerical Values	312
2.2.4.1.	The Static Characteristic Curve	312

## Introductory Remarks

### 1. Storing Matter and Dissipating Matter

Matter can be roughly visualized as a cluster of charged particles. Taken as a whole, they will usually show a neutral electric reaction, the partial charges compensating for each other. From the paired character of the charges required for compensation, two elementary models can be developed. In the first model, the individual charge pairs establish an internal bond each as shown in Fig. 1 as a primitive cluster of atoms: in the central fields of the nuclei electrons are orbiting around. In the second model (Fig. 2), electrons are moving freely between the nuclei. When external fields act on such systems of particles, they will become superimposed on the internal fields, affecting the patterns of motion. In the bonded-particle model, the effect of the fields results in changes in the inner bonding forces: field energy is stored in the particle system. In the second model, the freely movable electrons receive additional kinetic energy from the external field which is transferred to the ion cores by collisions: field energy is dissipated. This results in a rough classification of matter: a distinction is made between matter with energy-storing properties – “storing matter” – and matter with energy-dissipating properties – “dissipating matter.”<sup>1)</sup> The first category comprises accordingly substances with bonded charge carriers, the second covers substances with free charge carriers.

*The following considerations relate all to the class of “substances with bonded charge carriers.”*

Fig. 1.

Model of bonded particles in an external field.

Fig. 2.

Model of free particles in an external field.

<sup>1)</sup> Sometimes the terms *non-dissipative* and *dissipative* are used instead of the terms *storing* and *dissipating* which are employed in this book.

## 2. Some Phenomenological Considerations to the Reactions of Matter

The change in the bonding forces under the action of external fields produces a polarization of the particle system. Phenomenologically, the response of matter is described by the two constitutive relations

$$\vec{D} = \epsilon_0 \vec{E} + \vec{\Pi}_e(\vec{E}), \quad (1)$$

$$\vec{B} = \mu_0 \vec{H} + \vec{\Pi}_m(\vec{H}). \quad (2)$$

Their explicit field-dependent terms stand for the vacuum contributions to  $\vec{D}$  and  $\vec{B}$ , the other terms are the contributions of matter properly speaking:  $\vec{\Pi}_e$  and  $\vec{\Pi}_m$  denote the electric and the magnetic polarization. By way of these relations, the reactions of matter enter Maxwell's theory.

The polarizations can be further analyzed as:

$$\vec{\Pi}_e(\vec{E}) = N \vec{\pi}_e(\vec{E}) = \epsilon_0 \chi_e(\vec{E}) \vec{E}, \quad (3)$$

$$\vec{\Pi}_m(\vec{H}) = N \vec{\pi}_m(\vec{H}) = \mu_0 \chi_m(\vec{H}) \vec{H}. \quad (4)$$

The respective first equations establish a dependence of the polarizations on moments through the number of particles per unit volume,  $N$ . The granular structure of matter thus comes also into evidence in the phenomenological representation. The respective second equations, for which field dependence of the polarization already is a requisite condition, define the susceptibilities; these in turn determine the relative permittivities and permeabilities  $\epsilon$  and  $\mu$ , respectively:

$$\vec{D} = \epsilon_0 \left( 1 + \chi_e(\vec{E}) \right) \vec{E} = \epsilon_0 \epsilon(\vec{E}) \vec{E}, \quad (5)$$

$$\vec{B} = \mu_0 \left( 1 + \chi_m(\vec{H}) \right) \vec{H} = \mu_0 \mu(\vec{H}) \vec{H}. \quad (6)$$

As a rule, all parameters of matter are field-dependent quantities; the special type of field dependence is determined by the specific substance in each case. *Through the intermediary of these relationships, the entire multitude of linear and nonlinear processes in the interactions between fields and matter has its origin.*

In the following, the matter parameters of these phenomenological considerations will be the subject of detailed investigations. The approach is characterized by

- 1) The interpretation of their physical background.
- 2) The determination of the principal individual processes which come about from them.
