#### **Warranty Disclaimer**

This book has been compiled from literature data with the greatest possible care and attention. The statements made only provide general descriptions and information.

Even for the correct selection of materials and correct processing, corrosive attack cannot be excluded in a corrosion system as it may be caused by previously unknown critical conditions and influencing factors or subsequently modified operating conditions.

No guarantee can be given for the chemical stability of the plant or equipment. Therefore, the given information and recommendations do not include any statements, from which warranty claims can be derived with respect to DECHEMA e. V. or its employees or the authors.

The DECHEMA e. V. is liable to the customer, irrespective of the legal grounds, for intentional or grossly negligent damage caused by their legal representatives or vicarious agents.

For a case of slight negligence, liability is limited to the infringement of essential contractual obligations (cardinal obligations). DECHEMA e.V. is not liable in the case of slight negligence for collateral damage or consequential damage as well as for damage that results from interruptions in the operations or delays which may arise from the deployment of the Corrosion Handbook. This book was carefully produced. Nevertheless, editors, authors and publisher do not warrant the information contained therein to be free of errors. Readers are advised to keep in mind that statements, data, illustrations, procedural details or other items may inadvertently be inaccurate.

#### **Preface**

Practically all industries face the problem of corrosion – from the micro-scale of components for the electronics industries to the macro-scale of those for the chemical and construction industries. This explains why the overall costs of corrosion still amount to about 2 to 4% of the gross national product of industrialized countries despite the fact that zillions of dollars have been spent on corrosion research during the last few decades.

Much of this research was necessary due to the development of new technologies, materials and products, but it is no secret that a considerable number of failures in technology nowadays could, to a significant extent, be avoided if existing knowledge were used properly. This fact is particularly true in the field of corrosion and corrosion protection. Here, a wealth of information exists, but unfortunately in most cases it is scattered over many different information sources. However, as far back as 1953, an initiative was launched in Germany to compile an information system from the existing knowledge of corrosion and to complement this information with commentaries and interpretations by corrosion experts. The information system, entitled "DECHEMA-WERKSTOFF-TABELLE" (DECHEMA Corrosion Data Sheets), grew rapidly in size and content during the following years and soon became an indispensable tool for all engineers and scientists dealing with corrosion problems. This tool is still a living system today: it is continuously revised and up-dated by corrosion experts and thus represents a unique source of information. Currently, it comprises more than 8,000 pages with approximately 110,000 corrosion systems (i.e., all relevant commercial materials and media), based on the evaluation of over 100,000 scientific and technical articles which are referenced in the database.

Last century, an increasing demand for an English version of the DECHEMA-WERKSTOFF-TABELLE arose in the 80s; accordingly the DECHEMA Corrosion Handbook was published in 1987. This was a slightly condensed version of the German edition and comprised 12 volumes. Before long, this handbook had spread all over the world and become a standard tool in countless laboratories outside Germany.

Now that almost 20 years have passed since the first DECHEMA Corrosion Handbook was prepared for publication, it seems timely to publish a completely revised edition which takes into account the advances that have been made in the meantime. A large-scale research programme, which was funded by the German Federal

Ministry of Research and Development over a period of two decades and ended only a few years ago, played an important role in the discovery of much of this new knowledge. In addition, the international state-of-the-art has developed significantly and this has also been taken into account in the new edition, which is now called "Corrosion Handbook".

The general character of the handbook remains unchanged. The chapters are arranged by the agents leading to individual corrosion reactions, and a vast number of materials are presented in terms of their behaviour in these agents. The key information consists of quantitative data on corrosion rates coupled with commentaries on the background and mechanisms of corrosion behind these data, together with the dependencies on secondary parameters, such as flow-rate, pH, temperature, etc. This information is complemented by more detailed annotations where necessary, and by an immense number of references listed at the end of each chapter.

An important feature of this handbook is that the data was compiled for industrial use. Therefore, particularly for those working in industrial laboratories or for industrial clients, the book will be an invaluable source of rapid information for day-today problem solving. The handbook will have fulfilled its task if it helps to avoid the failures and problems caused by corrosion simply by providing a comprehensive source of information summarizing the present state-of-the-art. Last but not least, in cases where this knowledge is applied, there is a good chance of decreasing the costs of corrosion significantly.

Finally the editors would like to express their appreciation to Birgit Czack and Dr. Roman Bender for their admirable commitment and meticulous editing of a work that is encyclopedic in scope.

They are also indebted to Karin Sora and Dr. Barbara Boeck of Wiley-VCH for their valuable assistance during all stages of the preparation of this book.

Gerhard Kreysa and Michael Schütze

#### How to use the CORROSION HANDBOOK

The CORROSION HANDBOOK, abbreviated to CHB in the following, provides information on the chemical resistance and the corrosion behavior of materials in approximately 1000 different attacking chemical media and mixtures of materials.

The user is given information on the range of applications and corrosion protection measures for metallic, non-metallic inorganic, and organic materials, including plastics.

Research results and operating experience reported by experts allow recommendations to be made for the selection of materials and to provide assistance in the assessment of damage.

The objective is to offer a comprehensive and concise description of the behavior of the different materials in contact with a particular medium.

Every chapter is a self-contained work that is subdivided according to four groups of materials A-D:

- A Metallic materials
- . B Non-metallic inorganic materials
- C Organic materials and plastics
- D Materials with special properties

These material groups are each subdivided according to their chemical formula, the metals are classed according to different alloy groups. These groups are shown in the uniformly designed overview table at the start of each chapter.

Material recommendations are given for each of the four groups of materials. In more recent editions, these are summarized in the section

#### · E Material recommendations

The information on resistance is given as text, tables, and figures. The literature used by the author is cited at the corresponding point. There is an index of materials as well as a subject index at the end of the book so that the user can quickly find the information given for a particular keyword.

The CORROSION HANDBOOK is thus a guide that leads the reader to materials that have already been used in certain cases, that can be used or that are not suitable owing to their lack of resistance.

The resistance is coded with three evaluation symbols in order to compress the information. Uniform corrosion is evaluated according to the following criteria:

Symbol	Meaning	Area-related mass loss rate <sup>1)</sup>		Corrosion rate	
•		g/(m <sup>2</sup> h)	g/(m <sup>2</sup> d)	mm/a	
+	resistant	≤ 0.1	≤ 2.4	$\leq 0.1^{2}$	
$\oplus$	fairly resistant	< 1.0	< 24.0	< 1.0	
_	not resistant	> 1.0	> 24.0	> 1.0	

<sup>1)</sup> for AI, Mg, and its alloys, 1/3 of the value must be used

The evaluation of the corrosion resistance of metallic materials is given

for uniform corrosion or local penetration rate, in:

 $g/(m^2h)$  or  $g/(m^2d)$ . or if the density of the material is not known, in:

Pitting corrosion, crevice corrosion, and stress corrosion cracking or non-uniform attack are particularly highlighted.

The following equations are used to convert mass loss rates, x, into the corrosion rate, y:

from 
$$x_1$$
 into  $g/(m^2h)$  from  $x_2$  into  $g/(m^2d)$  where 
$$\frac{x_1 \cdot 365 \cdot 24}{\rho \cdot 1000} = \gamma \ (mm/a) \qquad \frac{x_2 \cdot 365}{\rho \cdot 1000} = \gamma \ (mm/a) \qquad x_1: \text{ value in } g/(m^2h) \\ x_2: \text{ value in } g/(m^2d) \\ \rho: \text{ density of material in } g/cm^3 \\ y: \text{ value in } (mm/a) \\ d: \text{ days} \\ h: \text{ hours}$$

In those media in which uniform corrosion can be expected, if possible, isocorrosion curves (corrosion rate = 0.1 mm/a) or resistance ranges for non-metallic materials are given. The evaluation criteria for non-metallic inorganic materials are stated in the individual cases; depending on the material and medium, they may also be given as corrosion rates (mm/a).

The suitability of organic materials is generally evaluated by comparing property characteristics (e.g. mass, tensile strength, elasticity module or ultimate elongation) and other changes (e.g. cracking) after exposure to the medium with respect to these characteristics in the initial state before exposure. The extent of changes in the properties after exposure to the medium is decisive for the evaluation of the resistance to chemicals or the durability of the materials. The criteria listed below for the evaluation of the chemical resistance apply to thermoplastics used to manufacture pipes and are based on results from immersion tests with an immersion time of 112 days (see ISO 4433 Part 1 to 4). In principle, they are also applicable to other organic materials; however, they should be adapted to the individual material,

<sup>&</sup>lt;sup>2)</sup> the values for Ta, Ti, and Zr are too high (possible embrittlement due to hydrogen absorption in the event of corrosion! Therefore, corrosion rate = 0.01 mm/a, see the individual cases)

because, as the following table shows, the evaluation criteria are not consistent, even within a group of thermoplasts, but depend on the type of thermoplastic material.

Symbol	Meaning	Permissible limiting value <sup>1)</sup>							
		of the mass change <sup>2)</sup> %	of the tensile strength <sup>3)</sup> %	of the elasticity module <sup>3)</sup> %	of the ultimate elongation <sup>3)</sup> %				
+	resistant/	PE, PP, PB:	PE, PP, PB,	PE, PP, PB:	PE, PP, PB:				
	durable	-2 to 10	PVC, PVDF:	≥ 38	≥ 50 to 200				
		PVC, PVDF:	≥ 80	PVC: ≥ 83	PVC, PVDF:				
		-0.8 to 3.6		PVDF: ≥ 43	50 to 125				
<b>⊕</b>	limited	PE, PB, PB:	PE, PB, PB,	PE, PB, PB:	PE, PB, PB:				
	resistance/	> 10 to 15 or	PVC, PVDF:	< 38 to 31	< 50 to 30 or				
	limited durability	< -2  to  -5	< 80 to 46	PVC: < 83 to 46	> 200 to 300				
	durability	PVC, PVDF:		PVDF: < 43 to 30	PVC, PVDF:				
		< -0.8 to $-2$ or		1 101. 1 15 10 50	< 50 to 30 or				
		> 3.6 to 10			> 125 to 150				
-	not resistant/	PE, PP, PB:	PE, PP, PB,	PE, PP, PB: <31	PE, PP, PB:				
	not durable	<-5  or > 15	PVC, PVDF:	PVC: < 46	< 30  or > 300				
		PVC, PVDF:	< 46	PVDF: < 30	PVC, PVDF:				
		< -2  or  > 10		1 1 1 1 1 . < 30	< 30  or > 150				

<sup>1)</sup> The data applies to the values determined in the initial state without exposure to the medium which correspond to 100 %

Unless stated otherwise, the data was measured at atmospheric pressure and room temperature.

The resistance data should not be accepted by the user without question, and the materials for a particular purpose should not be regarded as the only ones that are suitable. To avoid wrong conclusions being drawn, it must be always taken into account that the expected material behavior depends on a variety of factors that are often difficult to recognize individually and which may not have been taken deliberately into account in the investigations upon which the data is based. Under certain circumstances, even slight deviations in the chemical composition of the medium, in the pressure, in the temperature or, for example, in the flow rate are sufficient to have a significant effect on the behavior of the materials. Furthermore, impurities in the medium or mixed media can result in a considerable increase in corrosion.

The composition or the pretreatment of the material itself can also be of decisive importance for its behavior. In this respect, welding should be mentioned. The suitability of the component's design with respect to corrosion is a further point which must be taken into account. In case of doubt, the corrosion resistance should be investigated under operating conditions to decide on the suitability of the selected materials.

Relative mass change according to DIN EN ISO 175

Tensile strength, elasticity module, and ultimate elongation according to DIN EN ISO 527-1 Scope of validity for PVC: PVC-U, PVC-HI, and PVC-C; for PE: PE-HD, PE-MD, PE-LD, and PE-X

### Warranty disclaimer

This chapter of the DECHEMA Corrosion Handbook has been compiled from literature data with the greatest possible care and attention. The statements made in this chapter only provide general descriptions and information.

Even for the correct selection of materials and correct processing, corrosive attack cannot be excluded in a corrosion system as it may be caused by previously unknown critical conditions and influencing factors or subsequently modified operating conditions.

No guarantee can be given for the chemical stability of the plant or equipment. Therefore, the given information and recommendations do not include any statements, from which warranty claims can be derived with respect to DECHEMA e.V. or its employees or the authors.

DECHEMA is liable - regardless of the actual reason - for all damage caused by their official representatives and their employees on purpose or by gross negligence.

If there is only light negligence DECHEMA is only liable for infringing essential duties that arise from the use of the DECHEMA Corrosion Handbook ("cardinal duties"). DECHEMA can not be made liable for any indirect or subsequent damage and for any damage arising from production stops or delays, which are caused by using the DECHEMA Corrosion Handbook.
