This work develops the theoretical basis for an efficient method for the inductive calculation of the stable homotopy groups of spheres,  $\pi_*^S$ . Most of the steps of this method are algorithmic and are done by computer. We will apply this method to compute the first 64 stable stems. This method is based upon the analysis of the Atiyah-Hirzebruch spectral sequence:

(\*) 
$$E_{n,t}^2 = H_n BP \otimes \pi_t^S \Longrightarrow \pi_{n+t} BP.$$

 $H_*BP$  and  $\pi_*BP$  are well known. Moreover, the Hurewicz homomorphism  $h:\pi_*BP\longrightarrow H_*BP$  is a monomorphism. Therefore,  $E_{n,t}^{\infty}=0$  if  $t\neq 0$ , and  $E_{n,0}^{\infty}=h(\pi_nBP)$  which is also well known. If  $\pi_t^S$  is known for t< T then, with the exception of one step, it is algorithmic to deduce the composition series Image  $[d^r:E_{r,T-r+1}^r\longrightarrow E_{0,T}^r]$ ,  $2\leq r\leq T+1$ , of  $\pi_T^S$ . The determination of  $\pi_T^S$  from this composition series, the solution of the "additive extension problem", is accomplished using Toda brackets.

A distinctive feature of this method is that all the hard computations are done by computer. This includes the determination of differentials using Ouillen operations and the computation of

$$E_{N,t}^{r+1} = \text{Kernel } [d^r: E_{N,t}^r \longrightarrow E_{N-r,t+r-1}^r] \text{ / Image } [d^r: E_{N+r,t-r+1}^r \longrightarrow E_{N,t}^r].$$
 On the other hand there are two key steps which require human intervention in the computation of each  $\pi_T^S$ :

- (1) the matching of the list of "new" elements in degree T+1 which are hit by differentials with the list of "new" elements in degree T+2 on which nonzero differentials originate;
- (2) the solution of the additive extension problems.

Chapter 1 is devoted to the exposition of the background of this computation and to a detailed description of the method we will use. Even the most experienced reader should read the exposition of our notation for elements of the stable stems at the end of that chapter. In Chapter 2 we develop the three and four-fold Toda bracket methods which are used to solve extension problems. In Chapter 3 we give a global computation of the spectral sequence in the first eight rows. In higher rows our computations are inductive and rarely achieve a global understanding of the rows beyond the range of our computations. In Chapter 4 we recall some facts about the Image of J and use them to compute all the differentials which originate on  $E_{\underline{n}}^{n,0}$  for  $n \leq 70$ . Chapters 5 to 7 contain our calculations of the first 64 stable stems. In Chapter 8 we identify the elements  $\theta_4 \in \pi_{30}^S$  and  $\theta_5 \in \pi_{62}^S$  of Arf invariant one as well as the Mahowald elements  $\eta_{5} \in \pi_{32}^{S}$  and  $\eta_{6} \in \pi_{64}^{S}$ . The new proof that  $\theta_{5}$ exists and has order two is based upon Mahowald's ideas [34A] and the computations of this paper. It is a rewording of a detailed proof which Mahowald sent to me. We also show that  $\eta_{\rm E}$  has order four. We conclude with Appendices 1 - 4, 7 which contain tables that summarize and give references for all the computations of this paper. In the fifth appendix, we discuss the Fortran computer programs which are used in this computation. A copy of the program listings is available from the author. The most important output of these programs is contained in the last sections of Chapters 4 - 7. The sixth appendix depicts the mod 2 Adams spectral sequence through degree 64.

We will work exclusively at the prime two. Our methods, however, apply at all primes. Of course, the computations at odd primes would be very different from these computations at the prime two. In addition the size of the numbers involved at the prime two reached 2<sup>32</sup>, the limit of the computer, requiring the use of some multiprecision arithmetic. The computations at odd primes would involve much larger numbers.

I wish to thank The University of Western Ontario and York University for their support of this research as well as the University of Toronto for their hospitality during my sabbatical leave there. In addition, the Natural Sciences and Engineering Research Council of Canada supported this research through Operating Grants as well as an Equipment Grant which allowed the purchase of the IBM PC/AT computer on which the calculations were performed. Last, but not least, I am very grateful to Mark Mahowld for detecting errors in earlier versions of this paper, for his ideas on  $\theta_{\rm S}$  and for his assistance in constructing the Adams spectral sequence tables in Appendix 6.

#### CHAPTER 1: INTRODUCTION

#### 1. History of the Problem

The calculation of the stable homotopy groups of spheres is one of the most central and intractable problems in algebraic topology. In the 1950s Serre [57] used his spectral sequence to study this problem. In 1962, Toda [60] used his triple brackets and the EHP sequence to calculate the first 19 stems. These methods were later extended by Mimura, Mori, Oda and Toda [44], [45], [46], [50] to compute the first 30 stems. In the late 1950s the study of the classical Adams spectral sequence was begun [1]. Computations in this spectral sequence are still being pursued using the May spectral sequence and the lambda algebra. The best published results are May's thesis [39] and the computation of the first 45 stable stems by Barratt, Mahowald, Tangora [10], [37] as corrected by Bruner [16]. The use of the BP Adams spectral sequence on this problem was initiated by Novikov [49] and Zahler [62]. Its most spectacular success has been at odd primes [42]. A recent detailed survey of the status of this computation and the methods that have been used has been written by Ravenel [55].

An exotic method for computing stable stems was developed in 1970 by Joel Cohen [19]. Recall [20] that for a generalized homology theory  $\rm E_{*}$  and a spectrum X there is an Atiyah-Hirzebruch spectral sequence:

$$(1.1.1) E_{\mathbf{N},\mathbf{p}}^2 = H_{\mathbf{N}}(X; E_{\mathbf{p}}) \Longrightarrow E_{\mathbf{N}+\mathbf{p}}X.$$

Joel Cohen studied this spectral sequence with X an Eilenberg-MacLane spectrum and E equal to stable homotopy or mod p stable homotopy. His idea was to take advantage of the fact that in these cases the spectral sequence is converging to zero in positive degrees. Since the homology of the Eilenberg-MacLane spectra are known, one can inductively deduce the stable

stems. This is analogous to the usual inductive computation of the cohomology of Eilenberg-MacLane spaces by the Serre spectral sequence [17]. In that example, however, all the work can be incorporated into the Kudo transgression theorem. Joel Cohen was able to compute a few low stems, but the computation became too complicated to continue. His method was discarded since the Adams spectral sequence computations seemed much more efficient. In 1972, however, Nigel Ray [56] used this spectral sequence with X = MSU and E = MSp. He took advantage of the fact that H\*MSU and MSp\*MSU are known to compute the first 19 homotopy groups of MSp. Again this method was discarded since David Segal had computed the first 31 homotopy groups of MSp by the Adams spectral sequence and his computations were extended to 100 stems in [31].

My interest in Atiyah-Hirzebruch spectral sequences began in 1978. In a joint paper with Snaith [32] we studied the case where X is BSp and E<sub>\*</sub> is stable homotopy. The methods we developed there, in particular the use of Landweber-Novikov operations to study differentials, were clearly applicable to a wide class of examples. In 1983, I observed that if Joel Cohen's method were applied to the case where X is BP and E<sub>\*</sub> is stable homotopy then the computations would be greatly simplified over Cohen's case because of the sparseness of H<sub>\*</sub>BP and because Quillen operations could be used to compute the differentials. So, I began computing at the prime two. I soon discovered that the computations became too complicated to do by hand, but since they were mostly algorithmic they could be done by a computer. Using an IBM PC/AT micro-computer I was able to compute the first 64 stable stems. This work is the account of that computation.

Kaoru Morisugi informed me that in 1972 he attempted to use this method to compute  $\pi_*^S$  at the prime three, but he became bogged down with technical problems.

#### 2. The Brown-Peterson Spectrum and Quillen Operations

In this section we list some of the basic facts about the Brown-Peterson spectrum BP. The notation introduced here will be used throughout the computation.

Let MU denote the unitary Thom spectrum. By the Pontryagin-Thom isomorphism,  $\pi_* \text{MU}$  is isomorphic to  $\Omega_*^{\text{U}}$ , the ring of bordism classes of compact smooth manifolds without boundary which have a complex structure on their stable normal bundles. Using the Adams spectral sequence, Milnor [43] computed  $\pi_* \text{MU}$  to be a polynomial algebra over Z with one generator in each even degree. Brown and Peterson [15] discovered that when the spectrum MU is localized at a prime p, it decomposes into a wedge of various suspensions of a spectrum BP. This spectrum defines a generalized homology theory BP\* and a generalized cohomology theory BP\*. We list several basic properties of BP at the prime two. The standard references are the expositions of Adams [7] and Wilson [61].

- (1.2.1) There are  $M_N \in H_*BP$  of degree  $2(2^N-1)$  such that  $M_0 = 1$  and  $H_*BP = Z_{(2)}[M_1, \dots M_N, \dots].$
- (1.2.2) The Hurewicz homomorphism  $h: \pi_* BP \longrightarrow H_* BP$  is a monomorphism. Henceforth we consider h as an inclusion.
- (1.2.3) Define  $V_N \in H_*BP$  of degree  $2(2^N-1)$  recursively by  $V_0 = 2$  and for  $N \ge 1$ :

$$V_{N} = 2M_{N} - \sum_{k=1}^{N-1} M_{k} \cdot V_{N-k}^{2^{k}}.$$

The  $V_N$  /2, N  $\geq$  1, are polynomial generators for H\*BP. Moreover, all the  $V_N$  are in the image of h and  $\pi_*BP = Z_{(2)}[V_1, \ldots, V_N, \ldots]$ . The  $V_N$  are called the Hazewinkel generators [22], [23].

(1.2.4) BP BP is the algebra of BP-operations. These operations act on BP<sub>\*</sub>X for any spectrum X including BP<sub>\*</sub>S =  $\pi_*$ BP and BP<sub>\*</sub>KZ = H<sub>\*</sub>BP. These operations are natural. In particular, they commute with the Hurewicz homomorphism h.

- (1.2.5) BP\*BP =  $\pi_*$ BP[[  $r_\omega$  |  $\omega$  is a finite sequence of nonnegative integers]]. The  $r_\omega$  are called the Quillen operations [54]. They have the following properties.
- (a) The  $r_{(1)}$  are  $Z_{(2)}$ -module homomorphisms.
- (b) If  $f: X \longrightarrow Y$  is a map of spectra then  $f_* \circ r_\omega = r_\omega \circ f_*$ . In particular,  $h \circ r_\omega = r_\omega \circ h.$
- (c) If X is a ring spectrum and A,B  $\in$  BP $_{*}$ X then we have the Cartan formula

$$r_{\omega}(A \cdot B) = \sum_{\omega = \omega' + \omega''} r_{\omega'}(A) \cdot r_{\omega''}(B)$$

In [32] we showed how Landweber-Novikov operations act on the Atiyah-Hirzebruch spectral sequences for  $\pi_{\star}^{S}BU$  and  $\pi_{\star}^{S}BSp$ . The following theorem shows that the Quillen operations act on Atiyah-Hirzebruch spectral sequences for  $BP_{\star}X$ .

THEOREM 1.2.6 Let F be a ring spectrum. Consider the Atiyah-Hirzebruch spectral sequence for  $F_*BP$ :

$$E_{N,t}^2 = H_N BP \otimes F_t \Longrightarrow F_{N+t}$$

Then each Quillen operation  $\mathbf{r}_{\omega}$  of degree K induces a map of spectral sequences:

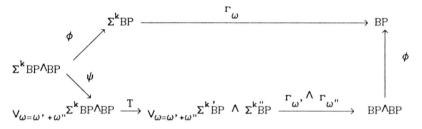

$$r_{\omega}: E_{N,t}^{s} \longrightarrow E_{N-K,t}^{s}.$$

These  $r_{\omega}$  have the following properties:

- (a) The  $r_{\omega}$  are  $Z_{(2)}$ -module homomorphisms.
- (b) The  $r_{\omega}$  are natural with respect to maps of spectral sequences induced by maps of spectra.
- (c) The  $r_{\omega}$  satisfy the Cartan formula  $r_{\omega}(A\cdot B) = \sum_{\omega=\omega'+\omega''} r_{\omega}, (A)\cdot r_{\omega''}(B) \text{ for all A, } B\in E^s.$
- (d) The action of  $r_\omega$  on  $E^2$  is given by  $r_\omega \otimes 1$  where the latter  $r_\omega$  is the usual Quillen operation on  $H_*BP$ .
- (e)  $d^s \circ r_\omega = r_\omega \circ d^s$  for all  $s \ge 1$ .

- (f) The action of  $r_{\omega}$  on  $E^{s+1}$  =  $H_*(E^s, d^s)$  is induced by the action of  $r_{\omega}$  on  $E^s$ .
- (g) The action of  $r_{\omega}$  on the  $E^s$  induce an action of  $r_{\omega}$  on  $E^{\infty}$  =  $\lim_{n \to \infty} E^s$ .
- (h) The action of  $r_{\omega}$  on  $E^{\infty}$  defined by (g) agrees with the action of  $r_{\omega}$  on  $E^{\infty}$  induced by the usual action of the Quillen operations on  $F_*BP = BP_*F$ .

PROOF. Since  $r_{\omega} \in BP^kBP$ , we can represent  $r_{\omega}$  by a map of spectra  $r_{\omega} \colon \Sigma^kBP \longrightarrow BP$ . Since the Atiyah-Hirzebruch spectral sequence is natural we have an induced map of spectral sequences. All of the properties are immediate except for the Cartan formula (c). It follows from the observation that the following diagram must commute up to homotopy:

In this diagram  $\phi$  is product map of BP and  $\psi$  is the pinching map. In each wedge summand k = k' + k'' and T is the switching map.

## 3. The Inductive Procedure

In this section we will describe in detail the inductive procedure that we will use to compute the stable stems. However, before we apply this procedure in Chapters 5 to 7 we will digress to compute the first eight rows of the spectral sequence in Chapter 3 and to study two of the basic ingredients of our procedure: Toda brackets in Chapter 2 and the image of J in Chapter 4. This section concludes with an exposition of the notation that we will use to denote the elements of  $\pi_*^S$ .

Consider the Atiyah-Hirzebruch spectral sequence:

(1.3.1) 
$$E_{N,t}^2 = H_N BP \otimes \pi_t^S \Longrightarrow \pi_{N+t} BP.$$

Since H\_BP is zero in odd degrees we see that in this spectral sequence:

$$E_{N,*}^{r} = 0 \text{ if N is odd,}$$

$$d^{2r+1} = 0 \text{ and}$$

$$E^{2r+1} = E^{2r+2} \text{ for all } r.$$

The Hurewicz homomorphism is given in terms of this spectral sequence by the following commutative square:

(1.3.3) 
$$\begin{array}{c}
\pi_{\mathbf{N}} \mathsf{BP} & \xrightarrow{h} & \mathsf{H}_{\mathbf{N}} \mathsf{BP} \\
\downarrow & & & & & \\
\mathsf{E}_{\mathbf{N},\mathbf{O}}^{\infty} > & & & & \\
& & & & & \\
\mathsf{E}_{\mathbf{N},\mathbf{O}}^{\infty} > & & & & \\
\end{array}$$

Since h is one-to-one, it follows that:

(1.3.4) 
$$E_{N,t}^{\infty} = \begin{cases} 0 & \text{if } t \neq 0 \\ \pi_{N}BP & \text{if } t = 0 \end{cases}$$
 and 
$$E_{N,t}^{\infty} = Z_{(2)}[V_{1}, \dots, V_{N}, \dots].$$

Thus, there must be nonzero differentials originating on the 0 row so that each monomial  $K(2^{-e}V_{M}^{e(1)}\cdots V_{M}^{e(M)})$  in  $E^2$  survives to  $E^\infty$  if and only if K is divisible by  $2^e$  where  $e=e(1)+\cdots+e(M)$ . We will prove in Chapter 4 that, in our range of computations, all nonzero differentials which originate on the 0 row land in ImJ  $\otimes$  H\*BP. We will assume that ImJ is known. The first step in our analysis of the spectral sequence (1.3.1) will be to compute all these differentials which originate on the 0 row in degrees 2 through 70. This computation is entirely algorithmic, is done by computer with no human assistance and is carried out in Section 4.4. The purpose of this computation is to record the cokernels of all of these differentials.

The behavior of the following elements in the spectral sequence is the key to the determination of differentials which originate above the 0 row.

DEFINITION 1.3.6 Let  $\phi \in \pi_t^S$  have order q and let  $V \in H_{2N}^B BP$ . Assume that:

- (a)  $\phi \cdot V \in E_{2N,t}^2$  survives to an element of  $E_{2N,t}^{2r}$  for some  $2 \le r \le \infty$ ;
- (b) if  $r = \infty$  then V = 0;
- (c) we know all differentials which originate or land on elements of  $E_{2k,t}^{2s}$  which have a representative in  $Z_q \phi \otimes H_* BP$  for all s and all  $0 \le k < N'$  where N' = N if  $r < \infty$  or  $N' = \infty$  if  $r = \infty$ .

We call such an element  $\phi \cdot V$  a  $\phi$ -leader.

Note: A  $\phi$ -leader can be zero. In that case our assumption is that we know all differentials which originate or land in  $Z_{\sigma}\phi \otimes H_{*}BP$ .

The following unfortunate phenomenon is the obstruction to using Theorem 1.2.6(e) to computing  $d^{2r}$ -differentials on  $\phi \cdot V$ ", degree V" > degree V, from the  $d^{2r}$ -differential on a  $\phi$ -leader  $\phi \cdot V$ .

DEFINITION 1.3.7 Let  $\phi \cdot V$  be a  $\phi$ -leader, and assume all the notation of Definition 1.3.6. A nonzero differential  $d^{2u}(\phi \cdot V')$  is callled a hidden differential if:

- (a)  $\phi \cdot V'$  is also a  $\phi$ -leader;
- (b) degree V' > degree V;
- (c) u < r.

Thus, if there is a hidden differential, the  $d^{2u}$ -differentials determined by  $d^{2u}(\phi \cdot V')$  must be computed before the  $d^{2r}$ -differentials determined by  $d^{2r}(\phi \cdot V)$  even though degree  $\phi \cdot V'$  > degree  $\phi \cdot V$ . The inductive computation of  $\pi_N^S$  now proceeds as follows. Assume that the information contained in the following induction hypothesis is known.

## (1.3.8) INDUCTION HYPOTHESIS

- (1) We know  $\pi_k^S$  for  $0 \le k < N$ .
- $$\begin{split} \text{(2}_{\text{N}}) \quad & \text{Write each nonzero differential on a $\phi$-leader $\phi$-$V$ $\in$ $E^{2r}_{2a,b}$, with \\ & \text{a+b} \leq \text{N, in the form d}^{2r}(\phi \cdot \text{V}) = \lambda \text{V'} \neq 0 \text{ where } \phi \in \pi^{\text{S}}_{b}, \ \lambda \in \pi^{\text{S}}_{b+2r-1}, \\ & \text{V} \in \text{H}_{2a} \text{BP and V'} \in \text{H}_{2a-2r} \text{BP.} \quad \text{Assume that we have "computed"} \\ & \text{d}^{2r}(\phi \cdot \text{V"}) = \sum \alpha_{_{1}} \lambda \text{ V}_{_{1}} \text{ for all V"} \in \text{H}_{2a} \text{"BP.} \end{split}$$
- (3<sub>N</sub>) For each  $\phi \in \pi_k^S$ , 0 < k < N, the  $\phi$ -leader of largest known degree is  $\phi \cdot V$  where either V = 0 or degree  $\phi \cdot V \ge N+1$ .

The information in  $(2_N)$  is called a "tentative differential table" and the information in  $(3_N)$  is called a "list of leaders". In condition  $(2_N)$ , the word computed is in quotation marks because what we assume that we have done is that we have computed  $r_\omega \circ d^{2r}(\phi \circ V'') = d^{2r} \circ r_\omega (\phi \circ V'')$  for all Quillen operations  $r_\omega$  of degree 2a"-2a. This would give an accurate computation of  $d^{2r}(\phi \circ V'')$  if there were no hidden differentials. Unfortunately, there are examples of hidden differentials.

To accomplish the inductive step we must go through the procedure below. We use the terminology "A  $\in E_{2N,t}^{2r}$  transgresses" if A survives to  $E^{2N}$ . In that case  $d^{2N}(A) \in E_{0,2N+t-1}^{2N}$ , a subquotient of  $\pi_{2N+t-1}^{S}$ .

#### (1.3.9) INDUCTION STEP

(a) Construct the following list of leaders of degrees N+1 and N+2:

Leaders in Degree N+1	<u>Leaders in Degree N+2</u>	ģ
$\alpha_{_{1}}$	$\boldsymbol{\beta}_{1}$	
	•	
•	• /	
•	•	
$\alpha_{ m p}$	$\beta_{ m q}$	

Each  $\alpha_i \in E_{2a(i),N-2a(i)+1}^{2a(i)}$  will either be hit by some  $\beta_j$  or it will transgress to determine a nonzero element of  $\pi_N^S$ . In either case  $\alpha_i$  transgresses to an element  $d^{2a(i)}(\alpha_i) = \hat{\alpha}_i \in \pi_N^S$ . In the former case  $\hat{\alpha}_i = 0$ , and in the latter case  $\hat{\alpha}_i \neq 0$ .

- (b) Search for hidden differentials  $d^{2u}(\beta) = \alpha_i$ , where  $d^{2r}(\beta) = \alpha'$  was one of the differentials in the tentative differential table of 1.3.8(2<sub>N</sub>). If a hidden differential is found then  $\alpha_i$  must be removed from the list in (a) and replaced with  $\alpha'$ . Assume that any necessary adjustments of this sort have been made to the list in (a).
- (c) Use Toda bracket methods from Chapter 2 and consequences of differentials which follow from Theorem 1.2.6(e) to make the following deductions:
  - (i) some of the  $\hat{\alpha}_{i}$  are zero;
  - (ii) some of the  $\beta_i$  transgress.

This step is complete when

card 
$$\{\alpha_i \mid \hat{\alpha}_i = 0\} = \text{card } \{\beta_j \mid \beta_j \text{ is not known to transgress}\}.$$

(d) Construct the following list of all  $\alpha_i$ ,  $\beta_j$  such that  $\hat{\alpha}_i = 0$  and  $\beta_j$  is not known to transgress:

There is a nonzero differential on each  $\beta_{j(k)}$  with image some  $\alpha_{i(h)}$ . Use Toda bracket methods from Chapter 2, consequences of differentials deduced from Theorem 1.2.6(e) and ad hoc monoid chain arguments to match which  $\beta_{j(k)}$ s hit which  $\alpha_{j(k)}$ s.

(e) Use Toda bracket methods from Chapter 2 to solve the additive extension problems to determine  $\pi_N^S$  from its composition series  $\{E_{0,N}^{2r}|1\leq r\leq [(N+1)/2]\}$ . This gives the information required in  $(1_{N+1})$ . This step is not absolutely
