## Preface

The discovery of the chemistry of aliphatic diazo compounds was made a century ago: Theodor Curtius synthesized ethyl diazoacetate in 1883 for the first time and with this opened the wide field of diazo chemistry, which even today has not yet been exhausted. The solution of the long controversial problem of constitution, the development of general and facile syntheses, and the application of diazo compounds in organic synthesis, facilitated by their incredible reactivity, have made this field a truly exciting one. Novel methods of synthesis, such as diazo group transfer and electrophilic diazoalkane substitution, and the most valuable contribution of diazo compounds to the chemistry of carbenes and cycloadditions indicate the continued interest in these compounds.

This monograph deals only with the properties and syntheses of aliphatic diazo compounds. Discussions concerning their reactions—if not absolutely necessary to describe certain aspects of their preparation—have been intentionally omitted in order to maintain the format. The first chapters deal with structure, spectroscopic properties, thermal behavior, acidic decomposition, and photochemistry of diazoalkanes, followed by synthetic methods. Further initiatives and developments may be expected, especially from the discoveries of novel diazoalkane syntheses. The Bibliography is intended to make entry into the tremendously growing literature on the subject easier.

This monograph was primarily written to be used by chemists interested in the synthetic application of diazo compounds and for colleagues with an interest in the physical properties of these compounds. We hope to stimulate

those who, like the authors, believe that the chemistry of diazoalkanes will continue to be nourished by the imagination of its disciples.

Throughout the various chapters of the book, the literature up to the end of 1982 has been reviewed. The major developments published up to January of 1986 are compiled concisely in an Addendum.

We are grateful to Professor Peter Stang, University of Utah, on whose suggestion this monograph was written. Our thanks are also extended to the editors and staff of Academic Press for their patience and helpfulness.

We appreciate very deeply the skillful preparation of the artwork by our co-workers B. Feith, O. Göttel, A. Kuhn, W. Lorenz, W. Rösch, B. Singer, and U. J. Vogelbacher. Furthermore, our thanks go to Mrs. H. Mai for the careful typing of the manuscript.

## **PART I      PROPERTIES OF ALIPHATIC DIAZO COMPOUNDS**

### **Chapter 1      Structure and Spectroscopic Properties**

1.1	The Constitution of Diazoalkanes	3
1.2	Structure and Bonding of Diazoalkanes	10
1.3	Cis–Trans Isomerism of the $\alpha$ -Diazocarbonyl Compounds	16
1.4	Metal Complexes with Diazo Compounds as Ligands	23
1.5	Spectroscopic Properties of Diazoalkanes	29
	References	58

### **Chapter 2      Thermal Properties**

2.1	Introduction	65
2.2	Alkyl and Aryl Diazomethanes	66
2.3	$\alpha$ -Diazocarbonyl Compounds	72
2.4	$\alpha$ -Diazophosphoryl Compounds	83
	References	93

### **Chapter 3      Reactivity toward Acids**

3.1	The Acid-Stability of Diazoalkanes	96
3.2	C- and N-Protonation	101

	3.3 Kinetics and Mechanism of the Reactions with Acids	105
	3.4 Influence of Solvent on Kinetics and Product Distribution	109
	3.5 Products of the Acid-Catalyzed Decomposition	114
	3.6 Diazocarbonyl Compounds and Lewis Acids	148
	References	161
<b>Chapter 4</b>	<b>Photochemistry of Aliphatic Diazo Compounds</b>	
	4.1 Introduction	166
	4.2 Diazoalkane–Diazirine Isomerization	167
	4.3 Generation of Carbenes from Diazo Compounds	170
	4.4 Wolff Rearrangement	185
	References	195
<b>PART II</b>	<b>SYNTHESES OF ALIPHATIC DIAZO COMPOUNDS</b>	
<b>Chapter 5</b>	<b>Diazotization of Amines</b>	
	5.1 Introduction	201
	5.2 Diazoalkanes	202
	5.3 Fluoro- and Cyanodiazoalkanes	202
	5.4 Diazocarbonyl Compounds	206
	5.5 $\alpha$ -Diazophosphoryl Compounds	213
	5.6 Diazoazoles	214
	References	217
<b>Chapter 6</b>	<b>The Forster Reaction</b>	
	6.1 Introduction	221
	6.2 Diazomethane and Aryldiazomethanes	221
	6.3 $\alpha$ -Diazoketones and Sulfones	223
	References	226
<b>Chapter 7</b>	<b>Introduction of the Diazo Group by Nitrosation</b>	
	7.1 Introduction	
	7.2 Diazoazoles	228
	7.3 Diazocarbonyl Compounds	230
	References	232
<b>Chapter 8</b>	<b>Dehydrogenation of Hydrazones</b>	
	8.1 Introduction	233
	8.2 Mercury(II) Oxide	236

8.3	Silver Oxide	246
8.4	Manganese(IV) Oxide	246
8.5	Lead(IV) Acetate	247
8.6	Iodine	250
8.7	Miscellaneous	252
	References	253
<b>Chapter 9</b>	<b>The Bamford–Stevens Reaction</b>	
9.1	Introduction	257
9.2	Aryl- and Alkyldiazoalkanes	263
9.3	Metallated Diazoalkanes	273
9.4	$\alpha$ , $\beta$ -Unsaturated Diazoalkanes	273
9.5	$\alpha$ -Diazocarbonyl Compounds	280
9.6	$\alpha$ -Diazophosphoryl Compounds	288
	References	292
<b>Chapter 10</b>	<b>Alkaline Cleavage of <math>\beta</math>-(<i>N</i>-Alkyl-<i>N</i>-nitrosoamino)ketones and -sulfones</b>	
10.1	Introduction	296
	References	298
<b>Chapter 11</b>	<b>Alkaline Cleavage of (<i>N</i>-Alkyl-<i>N</i>-nitroso-aminomethyl)carboxamides and -urethanes</b>	
	References	300
<b>Chapter 12</b>	<b>Acyl Cleavage of <i>N</i>-Alkyl-<i>N</i>-nitrosoacidamides</b>	
12.1	Introduction	301
12.2	Mechanism of Cleavage	301
12.3	<i>N</i> -Alkyl- <i>N</i> -nitrosourethanes	305
12.4	<i>N</i> -Alkyl- <i>N</i> -nitrosoureas	311
12.5	<i>N</i> -Alkyl- <i>N'</i> -nitro- <i>N</i> -nitrosoguanidines	316
12.6	<i>N</i> -Alkyl- <i>N</i> -nitrosocarboxamides	317
12.7	<i>N</i> -Alkyl- <i>N</i> -nitroso- <i>p</i> -toluenesulfonamides	322
	References	322
<b>Chapter 13</b>	<b>Diazo Group Transfer</b>	
13.1	Introduction	326
13.2	To Active Methylene Compounds	328
13.3	To $\alpha$ -Acylcarbonyl Compounds	372
13.4	Diazo Group Transfer to Alkenes	384

13.5	Diazo Group Transfer to Acceptor-Substituted Methylene Triphenylphosphoranes and Triphenylphosphonium Salts	401
13.6	Diazo Group Transfer to Alkynes	407
	References	427

*Part I*

**Properties of Aliphatic Diazo Compounds**

## Chapter 1

# Structure and Spectroscopic Properties

### 1.1 The Constitution of Diazoalkanes

When Curtius first synthesized ethyl diazoacetate via amine diazotation in 1883, no suggestion was made as to whether the  $\text{CN}_2$  group was in a cyclic [e.g., diazirine **1** ( $\text{R} = \text{H}$ )] or an open (**2**,  $\text{R} = \text{H}$ ) configuration (*1*). Some years later, however, he postulated structure **1** for  $\alpha$ -diazoesters,  $\alpha$ -diazoamides, and the salts of the free acids (*1a*). The cyclic structure was adopted for diazomethane by v. Pechmann, who had synthesized the compound by base cleavage of *N*-methyl-*N*-nitrosourethane in 1894 (*2*).

**1**

**2**

**3**

Thiele finally suggested open configuration **3** for diazoalkanes in 1911 (*3*); it contains, according to the valence theory accepted then, a pentavalent nitrogen atom. His reasoning is based on the experimental results that diazo compounds are formed by dehydrogenation of hydrazones, compounds whose open constitution was well known.

Neither chemical properties of diazo compounds nor measurements of the parachor or dipole moment of diazomethane could end the long-lived discussion over the “true” structure. An electron diffraction experiment by Boersch in 1935 finally decided the issue in favor of an open diazomethane

molecular structure with linear geometry of the  $\text{CN}_2$  group (4). Only in 1957, did a chemical experiment prove the open structure for ethyl diazoacetate as well (5). Ethyl glycinate was diazotized with  $^{15}\text{N}$ -labeled sodium nitrite, and the labeled ethyl diazoacetate reductively cleaved to glycine and ammonia. It was to be expected that in the case of a linear arrangement of the diazo group,  $^{15}\text{N}$  would be released exclusively as ammonia, whereas for a cyclic arrangement a statistical distribution of the label between both reduction products should result. Analyses unambiguously decided in favor of the open structure.

Since 1960, straightforward routes to synthesize the cyclic valence isomer of diazomethane, diazirine **4** ( $\text{R}^1 = \text{R}^2 = \text{H}$ ), and derivatives, have been discovered (6,7). This has made it possible to compare both classes of compounds directly: diazirines are (almost) colorless and most diazoalkanes are intensely yellow to red; diazirines are far less reactive than diazoalkanes (e.g. they are stable against acids), whereas sensitivity to acids is one of the most pronounced properties of most diazoalkanes (see Chapter 3, Section 1).

When suitable substituents are present, the valence isomerization diazoalkane-diazirine is possible in both directions. Upon irradiation of diazirine (**8**) ( $\lambda = 320 \text{ nm}$ ), 3-aryl-3*H*-azirines (**8a**) ( $\lambda \geq 280 \text{ nm}$ ), cycloalkanespirodiazirines (**8b**) ( $\lambda \geq 310 \text{ nm}$ ) or 3-*n*-butyl-3-phenyldiazirine (**8c**) ( $\lambda \geq 330 \text{ nm}$ ), isomerization to the corresponding diazoalkane competes with fragmentation into carbene and  $\text{N}_2$ . In these cases, diazoalkane formation was proved by trapping reactions, spectroscopically, or by the isolation of products that stem from diazoalkane reactions. In other examples, the intermediacy of diazoalkanes in thermal or photochemical reactions of diazirines was deduced from kinetic evidence or isotope labeling experiments (**8d**). 3,3-Diphenyldiazirine probably rearranges to diazodiphenylmethane in the presence of oxygen or mercury(II) oxide during its attempted synthesis (9). On the other hand,  $\alpha$ -diazoamides (**5**) with a hydrogen atom at the diazo carbon will isomerize to the corresponding diazirinecarboxamides when irradiated with visible light (10,11).

A reversible photochemical rearrangement of diazirine **6** and diazoalkane **7** is possible by selecting the appropriate wavelength. At 310 nm, **6** is converted to **7**; at 410 nm, the reverse reaction takes place. To some extent, carbenes are formed by  $N_2$  elimination from the two valence isomers and undergo subsequent reactions (12).

Examples of the thermal reversion of a photoisomerization are also known. Ultraviolet irradiation of 3-diazo-2,3-dihydro-2-indolone (3-diazo-2-oxindoline) and its *N*-methyl derivative **8** leads to the pale yellow diazirines **9**, which rearrange, even at room temperature, to the red diazo compounds **8** (13). The activation parameters of  $9 \rightarrow 8$  ( $R = \text{CH}_3$ ) were determined as:  $\Delta H^\ddagger = 110.9 \text{ kJ mol}^{-1}$  (26.5 kcal mol $^{-1}$ ),  $\Delta S^\ddagger = 40.6 \text{ J K}^{-1} \text{ mol}^{-1}$  (9.7 cal K $^{-1}$  mol $^{-1}$ ).

Isopropylidene diazomalonate **10** and the isomeric diazirine **11** show similar behavior (14).

Scheme 1.1

It is not surprising that the thermal valence isomerization diazoalkane  $\rightarrow$  diazirine has not yet been observed. Diazirine is higher in energy than diazomethane by a margin of  $\sim 126 \text{ kJ mol}^{-1}$  ( $30 \text{ kcal mol}^{-1}$ ), according to the heats of formation obtained by mass spectrometric analysis (15,15a).

At a time when the structure of diazomethane was still in doubt, Müller and Kreutzmann (16) discovered another isomer. By treating the sodium salt of diazomethane in ether with acetic acid, a pale yellow solution is formed that no longer contains diazomethane but a new substance with unpleasant odor. The authors called the compound “isodiazomethane” but gave no suggested structure. Further investigations indicated the compound to be a tautomer of diazomethane, and it was finally characterized as *N*-isocyanamine (12) because of the equivalency of both protons in the  $^1\text{H}$ -NMR spectrum (17–19).

Scheme 1.1 demonstrates the reversible tautomerization of diazomethane and *N*-isocyanamine, which takes place via a common tautomerizable anion.

For a long time there was a similar ambiguity in the constitution of  $\alpha$ -diazocarbonyl compounds. Wolff (20) synthesized the compounds for the first time by diazotization of the  $\alpha$ -amino derivatives of  $\beta$ -keto esters, or 1,3-diketones with sodium nitrite in dilute sulfuric acid solution. Because of their remarkable acid stability (see Chapter 3, Section 1), the open structure **13** seemed unlikely. Instead, Wolff suggested the structures of “diazoanhydrides,” such as compounds of the type **14** (1,2,3-oxadiazoles). However, such heterocycles have not been isolated yet.
