## PREFACE

The 5th Biennial Conference on "*Waves and Stability in Continuous Media*" was held in Sorrento (Italy) from October 9 to 14, 1989. Same as the previous four conferences this was a gathering of researchers who are interested in discussing and presenting current problems on Waves and Stability in Continuous Media. The scientific program included about twenty invited speakers and short contributed papers.

The warm atmosphere created during the Conference has produced a deep interchange of ideas and new common projects in this area.

The success of the Conference was due to the generous financial support of several agencies that are listed in p. viii.

I wish to thank the members of both the Scientific and Organizing Committee as well as the members of the Organizing Secretariat for their help.

Last, but not least, I must acknowledge the participation of so many registrants from different countries. Their collaboration was essential for the success of the Conference.

*Salvatore Rionero*

## CONFERENCE SPONSORS

The organization of the 5th International Conference on Waves and Stability in Continuous Media was made possible by the financial support of:

Mathematical Committee of the Italian National Research Council (C. N. R.)

Gruppo Nazionale per la Fisica Matematica (G. N. F. M.-C. N. R.)

Gruppo Nazionale M. P. I. 40% Problemi di Evoluzione nei fluidi e nei solidi  
Universita' di Napoli "Federico II"

Dipartimento di Matematica ed Applicazioni "R. Caccioppoli"

Istituto Italiano per gli Studi Filosofici

Istituto per le Applicazioni della Matematica del C. N. R. (Naples)

# ON STABILITY AND LONG TERM BEHAVIOUR FOR RAREFIED GASES

LEIF ARKERYD

Department of Mathematics

Chalmers University of Technology

and the University of Göteborg

S-41296 Göteborg Sweden

## ABSTRACT

The talk discusses the stability and long term behaviour of rarefied gases modeled by the Boltzmann equation. A review of results for initial values far from equilibrium is given.

## A Formal Discussion

Let us consider a rarefied gas described through its one particle density  $F$  in phase space. Back in 1872 Boltzmann gave the evolution of such a gas through an equation which expresses the material derivative of  $F$  in terms of the gain from molecules colliding into a region by binary collisions minus the loss from those colliding out of the region. In the absence of exterior forces his equation is

$$\partial_t F + v \nabla_x F = \text{gain} - \text{loss} = QF.$$

Here  $\nabla_x$  is the gradient with respect to the space variable  $x$ ,  $v$  is velocity and  $t$  is time. Finally  $Q$  is the so called collision operator,

$$QF(x, v_1) = \int_{\mathbb{R} \times \mathbb{B}} (F(x, v'_1)F(x, v'_2) - F(x, v_1)F(x, v_2))k(v_1, v_2, u)dv_2du.$$

Given two molecules of initial velocities  $(v_1, v_2)$  and initially separated in space,  $(v'_1, v'_2)$  denotes the velocities after collision. The details of the collision process are described with the help of the parameter set  $B$ , which is often chosen as angular coordinates for a sphere. Finally  $k$  is a weight function depending on the interaction between the molecules.

On physical grounds, the gas left to itself should settle down towards some equilibrium, and that in a stable way, i.e. gases with a similar initial preparation should approach similar equilibria in a similar way. And of course, this ought to be mirrored by the solution  $F$  of the Boltzmann equation model. Surprisingly, after the equation has been around for almost 120 years, the mathematical understanding of these questions is still far from complete. For the great variety of more complicated phenomena such as shocks, bifurcations and waves, which in many cases are fairly well understood on the gas dynamic level, any more fundamental kinetic studies have hardly even started, and for a reasonable picture above the perturbation level, we can only put our hopes to the future.

Before turning to the mathematical results on equilibrium and stability, let us see what the Boltzmann equation seems to tell us formally about the long time behaviour. Consider the entropy

$$HF(t) = \int F(t) \log F(t) dx dv.$$

We have

$$(\partial_t + v \nabla_x)(F \log F) = (\partial_t + v \nabla_x)F + \log F (\partial_t + v \nabla_x)F = QF + \log F \cdot QF,$$

and (by a change of variables argument)

$$\int QF dx dv = 0.$$

Hence, under suitable boundary conditions

$$\begin{aligned}
 (1) \quad \partial_t \int F \log F \, dx dv &= \int (\partial_t + v \nabla_x) F \log F \, dx dv = \int Q F \, dx dv + \int \log F \cdot Q F \, dx dv \\
 &= \int \log F \cdot Q F \, dx dv = (\text{change of variables}) \\
 &= \frac{1}{4} \int (F'_1 F'_2 - F_1 F_2) (\log F'_1 F'_2 - \log F_1 F_2) k \, dx dv \leq 0.
 \end{aligned}$$

And so the entropy is decreasing. By a similar change of variables, mass, v-moments, and energy can be seen to be conserved. Finally a lemma by Gibbs tells us that the entropy is bounded from below by its value for a certain maxwellian  $E_0 = a \exp(-b|v|^2 + (c \cdot v))$  depending on the initial value.

Integrating (1) with respect to time we formally get

$$\begin{aligned}
 \int E_0 \log E_0 \, dx dv &\leq \int F(t) \log F(t) \, dx dv = \int F_0 \log F_0 \, dx dv - \\
 &- \frac{1}{4} \int_0^t \int (F'_1 F'_2 - F_1 F_2) (\log F'_1 F'_2 - \log F_1 F_2) k \, dx dv ds,
 \end{aligned}$$

and so

$$F'_1 F'_2 - F_1 F_2 \rightarrow 0 \text{ as } t \rightarrow \infty.$$

As mentioned above we also expect  $F$  to converge to some equilibrium  $w$ , which should then satisfy  $w'_1 w'_2 - w_1 w_2 = 0$ . This gives for  $f = \log w$  that

$$f(v'_1) + f(v'_2) = f(v_1) + f(v_2).$$

Essentially by arguments going back to Cauchy, it follows that

$$f = \alpha + (v_0 \cdot v) - \beta |v|^2, \quad w = \exp(f) = a \exp(-b|v|^2 + (v_0 \cdot v))$$

with coefficients possibly depending on other variables such as  $x$  and  $t$ . Hence the equilibrium is a (possibly local) maxwellian.

In the case of the forces between the molecules being inversely proportional to the fifth power of the distance, the v-moments formally satisfy a system of ordinary differential equations which can easily be analysed having exponential convergence to equilibrium and stability.

## Strict Results

The formal arguments indicate the presence of convergence to equilibrium, even exponential convergence, and stability. When we next turn to the strict mathematical results and starting far from equilibrium, we will see that the strength of the known results steadily decreases, when progressing from a) the spacehomogeneous case via b) the spacedependent case close to spacehomogeneous to c) the spacedependent case in general.

In the spacehomogeneous case a) the understanding is good for hard forces, i.e. those of inverse power  $>5$  under suitable cutoffs in the  $u$ -variable, which means playing down the grazing collisions. Let

$$k(v_1, v_2, u) = h(u) |v_1 - v_2|^\beta, \quad 0 < \beta \leq 1, \text{ with } h \text{ bounded,}$$

$$L_r^1 = \{\text{measurable functions } f \text{ with } (1+|v|^r)f \in L^1(\mathbb{R}^3)\},$$

$$L_{r\gamma}^1 = \{f: \mathbb{R}_+ \rightarrow L_r^1 \text{ with } \sup_{t>0} \exp(\gamma t) \|f(t)\|_r < \infty\}.$$

Given a maxwellian  $E_0$  the following result holds.

**Theorem** <sup>1)</sup> There exists  $r_0 > 2 + \beta$ , and  $\mu > 0$ , such that if  $r_1 \geq r_0$  and

$$F_0 \in L_{r_1}^1, \quad \int (1, v, v^2) F_0 dv = \int (1, v, v^2) E_0 dv, \quad F_0 \log F_0 \in L^1,$$

then

$$\|F - E_0\|_{r, \gamma} < \infty \quad \forall r < r_1, \quad 0 \leq \gamma < \mu.$$

Moreover, if  $2 \leq r \leq r_1 - \beta$ , then given  $\varepsilon > 0$ , and a bounded set  $B \subset L_{r_1}^1$ ,

there is a  $\delta > 0$  such that (stability)

$$\sup_{t>0} \|F - \tilde{F}\|_{r, 0} < \varepsilon \quad \text{if} \quad \|F_0 - \tilde{F}_0\|_r < \delta \quad \text{and} \quad \tilde{F}_0 \in B.$$

The proof uses the spectral properties of the linearized collision operator and a powerful a priori estimate for  $Q$ . It is fairly technical and the interested reader is referred to the article <sup>1)</sup>.
