Preface

Research needs ideas, discourse and experimentation in order to thrive, but more than ever we are expected to make research immediately ‘relevant’ and available to society and the world of commerce. Of these three poles (ideas, discourse and experimentation), ideas lie farthest from a finished product, and it is therefore ideas that are most easily left behind in the rush to catch the gravy train. The pressure to prioritize applications rather than understanding hinders researchers from thinking deeply about problems, and in the worst case prevents us from truly understanding and innovating.

The first Autonomous Infrastructure Management and Security conference (AIMS 2007) was proposed as an act of optimism by the leaders of the EMANICS Network of Excellence in Network and Service Management. It was a proposal aimed at avoiding the tar-pit of “apply existing knowledge only, ” to reach out for new ideas that might expand our network of concepts and solutions.

There are already many excellent conferences in the field of Network of System Management : LISA, IM, NOMS, DSOM, Policy Workshop, etc. Although there is an overlap, both in attendance and ideas, AIMS does not compete with any of these. Rather we have sought a strong cross-disciplinary forum, in which novelty and discussion are made paramount. An additional objective of AIMS is to provide a forum for doctoral students, the future leaders of our research, to discuss their research with a wider audience and receive training to help make their research careers successful. To this end, AIMS incorporates a European PhD Student Symposium and a tutorial programme that covers a broad range of topics.

We have sought sometimes bold or ambitious ideas, even those that are unfinished, and this naturally invites controversy. We have ensured nevertheless the highest standard, and each paper in this volume has received not merely acceptance, but at least one enthusiastic endorsement from a referee. For the main track, 58 submissions were received and 14 were accepted. For the European PhD symposium, 31 submissions were received and 18 accepted. Of the 15 tutorials proposed, ten were provided.

The AIMS conference was arranged and sponsored by the IST EMANICS Network of Excellence (#26854), in cooperation with the ACM. This yielded an established network of experts in the field of network and service management. Networks are not static of course, they grow as meaningful dialogue pushes at the borders of the established connections, spreading into other fields. Where should one draw the borders of a network? This is a question that some of our contributors have asked in their work. Canright and Engø-Monsen tell us that the natural borders in a network can be defined where dialogue stops, and one-way communication begins. So we have fashioned the AIMS conference around dialogue, not just presentation. With short presentations and extensive, guided

discussion of each paper, it is our goal to capture the spirit of scientific discourse, and to inspire and propel the PhD students to be the next generation of experts in our field.

We would like to thank everyone who gave their time to the project, either as a contributor or as an organizer. We are grateful to the Programme Committee, reviewers and to the organizers of students symposium and tutorial tracks for their efforts. Most of all we thank the authors of the papers for allowing us to realize the goal of our conference.

During the conference, we also benefited from student volunteers and behind-the-scenes administrators who mobilized the conference smoothly and seamlessly. The conference was supported by the EMANICS Network of Excellence (<http://www.emanics.org>).

Organization

AIMS 2007 was organized by the EC IST-EMANICS Network of Excellence (#26854) in cooperation with ACM SIGAPP, SIGMIS and Oslo University College.

Main Conference Chairs

Arosha Bandara	Open University, UK
Mark Burgess	Oslo University College, Norway

Student Symposium Chair

Rolf Stadler	Royal Institute of Technology, Sweden
--------------	---------------------------------------

Tutorial Coordinators

Isabelle Chrisment	LORIA, France
David Hausheer	University of Zurich, Switzerland

Student Symposium Technical Programme Committee

Rolf Stadler	Royal Institute of Technology, Sweden
Gyorgy Dan	Royal Institute of Technology, Sweden
Emil Lupu	Imperial College London, UK
Joan Serrat	Universitat Politècnica de Catalunya, Spain
Burkhard Stiller	University of Zurich, Switzerland
Felix Wu	University of California Davis, USA

Local Arrangements

Conference Coordinator	Mark Burgess
Finance Coordinator	Marianne Kjær Bakke
Travel and Finance Coordinator	Gro Birgitte Ruste
Marketing Liason	Kjersti Hilden Smørvik
Conference Registration	Jon Ørstavik
Conference Design	Mark Burgess

Technical Programme Committee

Arosha Bandara	The Open University, UK

Abstract. JMX (Java Management eXtension) is a Java framework that allows any Java technology-based application or accessible resource to become easily manageable. This standard begins to be widely used within different managed systems which vary from large mainframes to small mobile devices, limited in both resource and computing capacity. Today, little is known about the costs associated with the manageability of a system. In this paper, we analyse the impact of various instrumentation models on the behavior of both the functional and the management plane. We show on a JMX instrumented web server that the service is highly affected by the management activity in driver and component models while a daemon approach limits the management impact on the functional service.

Keywords: JMX, Agent, Daemon, Driver, Component, Benchmarking, Management Performance.

1 Introduction

The Java technology deployment varies from small devices to huge data centers with a considerable number of servers. The functionality that controls these applications work is split into two main planes: (i) a value-added plane or *functional plane* that handles the users data ; (ii) the management plane that monitors and configures the functional plane. While the original functional plane was designed to be independent from the management plane, today's applications and services are far more integrated and more complex than before. The functional plane needs to expose both client's services and management interfaces.

Another important trend over the past couple of years is the emergence of the JMX standard for managing Java based applications, mainly the J2EE applications [3]. This standard aims to provide a management architecture and an

API set that allows any Java technology-based or accessible resource to be inherently manageable. As the number of resources being managed grows and the systems become more distributed and more dynamic, the behavior of application management technologies such as JMX needs to be studied. The overhead of management activities could be important on the user perceived performance of a JMX based managed applications such as a web server where delays and throughput are the key performance metrics for quality of service guarantee [11].

In the past few years, several works [11,1,5] have looked at the performance of multi-tier Internet services which are the base of many businesses, such as retailers, auctioneers and banks. Most of them focus on studying their performance independently from the existence of the management tier. Therefore there is a need to study the performance of such Internet applications accounting for the behavior of the management tier.

Little is known about the cost associated with JMX based management activities. To assess these costs, it is necessary to collect data about the performance and operations of this management system. Furthermore, it is important to collect this data under various configurations and management assumptions. One aspect of these management configurations is the integration model of a JMX agent within a managed system. In the literature, three integrations models are proposed: *daemon*, *driver* and *component* [8]. Overhead associated with management activities of those three models on a managed system performance is unavoidable apart from switching off any instrumentation. However, basic questions we are trying to answer arise: *Does the three models impact differently a managed system performance ? Does it also impact the management part's performance ? Which model is more appropriate and in which context ?*

The main contribution of this paper is to present an experience report on the design and implementation of a simple benchmark to evaluate the three integration models and their impact on the user perceived delays and throughput of the managed web server. In complement to the work in [9], we compared the three models against the same managed application which is a small Java based web server (Tiny Java Web Server¹) to derive credible performance assessment within comparable experimental environment. This could be helpful for JMX based management systems designers to select one of them regarding performance metrics guarantee. The remainder of this paper is organized as follows. Section 2 gives an overview of the three integration models of a JMX agent. Section 3 describes our benchmarking methodology to assess the impact of the three models. Section 4 analyses the obtained empirical results. Section 5 presents concluding remarks.

2 JMX Agent Integration Models

A common paradigm for traditional management systems and even for the autonomic management framework [7] is the manager-agent model [8]. The JMX management framework [10] is based on this model. In this model, agents mediate between managed devices or services, and managers. An agent is responsible

¹ see: <http://sourceforge.net/projects/tjws/>

for processing requests from managers, gathering responses, returning them to the requester and issuing notifications when registered events occur. The JMX agent, or MBean server, satisfies the definition and requirements of a management agent. Its functionality is to control the resources and make them available to remote management applications. According to the JMX specification, the JMX agent is composed of the MBean server, MBeans mapped on managed resources, agent services and adaptors or connectors. Basically the MBean server is a registry of objects that provide to the managers the attributes and operations through which the resources are monitored. On the other side, the manager is responsible for collecting management information from the agents using one of the two modes: polling or notification, and then takes any defined automated actions or solicits a human decision. The JMX API does not provide a specification for a manager, but it supplies all necessary requirements to design and develop a full management system. We are mostly interested in the deployment of the management agent in the managed resource. The main question here is: *how can a new or an existing application be designed in order to become manageable*. Therefore we implemented the three agent integration models identified by the authors of [8]: *daemon*, *driver* and *component*.

2.1 Daemon Model

In the daemon model as depicted in figure 1(a), the JMX agent and the managed application are running in two separate processes. The managed application is not influenced by the overhead imposed by the JMX implementation. Therefore in case of low utilization by the JMX agent, the performance of default functionality should not be affected. One advantage of using the daemon model is that the system can have a single MBean server available for multiple applications. Due to its existence outside the scope of managed applications, the MBean server can be used to control the life-cycle of the application or possibly many applications. On the other hand, problems may arise when the applications try to find or use the MBean server.
