FOR INSTRUCTORS AND STUDENTS

How Did I Become Involved with Environmental Problems? In 1966, I heard a scientist give a lecture on the problems of overpopulation and environmental abuse. Afterward I went to him and said, "If even a fraction of what you have said is true, I will feel ethically obligated to give up my research on the corrosion of metals and devote the rest of my life to research and education on environmental problems and solutions. Frankly, I don't want to believe a word you have said, and I'm going into the literature to try to prove that your statements are either untrue or grossly distorted."

After 6 months of study I was convinced of the seriousness of these problems. Since then, I have been studying, teaching, and writing about them. This book summarizes what I have learned in more than three decades of trying to understand environmental principles, problems, connections, and solutions.

Major Features This book is designed for introductory courses on *environmental science*. It treats environmental science as an *interdisciplinary* study, combining ideas and information from (1) *natural sciences* (such as biology, chemistry, and geology) and (2) *social sciences* (such as economics, politics, and ethics) to present a general idea of how nature works and how things are interconnected. It is a study of *connections in nature*.

This book is

- **Science based.** A total of 96 pages (25% of this book) are devoted to using basic scientific and ecological concepts, laws, and principles to enable students without prior scientific training to understand and think critically about environmental problems and solutions.
- **Balanced.** Great emphasis placed on (1) giving balanced presentations of opposing viewpoints on controversial environmental issues and (2) helping students think critically and decide such issues for themselves. Both *good news* and *bad news* on our progress in dealing with environmental problems are presented.
- **Solutions oriented.** A total of 147 pages are used to list and evaluate solutions to environmental problems.
- **Focused on visual learning.** The book's 285 illustrations (109 of them new to this edition) have been carefully designed to present complex ideas in understandable ways and to relate learning to the real world. Learning is also stimulated by use of special boxes throughout the text. They include (1) *Pro/Con boxes* that present both sides of controversial environmental issues, (2) *Connections boxes* describing connections in nature and between environmental concepts, problems, and solutions, (3) *Solutions boxes* summarizing a variety of solutions to environmental problems proposed by various analysts, (4) *Spotlight boxes* that highlight and give insights into key environmental problems and concepts, and (5) *Individuals Matter boxes* that describe what people have done to help solve environmental problems.
- **Current and accurate.** This book is updated every two years. In preparing each new edition I typically review about 10,000 printed references and thousands of websites.
- **Internet integrated.** The icon  is used to link material in the book to our interactive website at <http://www.brookscole.com/product/0534385354s>. At this website, which is updated constantly, you will find Cool Events, Critical Thinking Questions, Tips on Surfing, Interactive Quizzes for each chapter, and much more. Students and instructors also have access to *InfoTrac*® College Edition, a searchable online database of recent articles from more than 700 periodicals.

To reduce student costs, this book is printed in black-and-white and has a soft cover. It is also printed on acid-free recycled paper with the maximum content of postconsumer waste currently available at an affordable cost.

Instructors who want books covering this material with a different emphasis, organization, and length can

use one of my two other books written for various types of environmental science courses

- *Living in the Environment*, 12th edition (758 pages, Brooks/Cole, 2002)
- *Environmental Science*, 8th edition (549 pages, Brooks/Cole, 2001, a shorter version of *Living in the Environment*)

Major Changes in the Fifth Edition *This is the most significant revision since the first edition came out. Detailed changes by chapter are listed in the annotated material in the front of the instructor's version of this book and on this book's website. Major changes include the following:*

Content

- Updated and revised material throughout the book.
- 25 new reviewers to improve content and balance.
- 109 new or improved figures.
- 22 Pro/Con diagrams summarizing a large amount of complex information about the advantages and disadvantages of various solutions to environmental problems in a balanced, easy-to-understand manner. Examples include Figures 4-28 (p. 121), 4-41 (p. 131), 4-46 (p. 135), 7-21 (p. 226), and 11-10 (p. 345).
- 125 new topics. Examples include the following: (1) ecological footprints of countries (Figure 1-8, p. 7); (2) ecological and economic services provided by terrestrial and aquatic systems, examples include Figure 2-39 p. 56 and Figure 2-42 p. 59; (3) precautionary principle (p. 72); (4) genetically modified food (pp. 219-222); (5) drip irrigation (p. 309); (6) using the internet to save energy and reduce global warming (p. 112); (7) hybrid gas-electric and fuel-cell car engines (p. 109); (8) micropower electricity production (p. 139); (9) selling services instead of goods (p. 336); (10) sustainable timber certification (p. 153); (11) biodiversity hot spots (p. 168); (12) smart urban growth (pp. 98-99); and (13) failure of Biosphere 2 (pp. 378-379).

Learning Aids

- Greater use of numbered and bulleted lists to make the book simpler and help students comprehend and review key material.
- Use of questions as titles for all subsections to spark interest and serve as a built-in list of learning objectives for readers.

- Cross-references by page number to link concepts and material throughout the book. This (1) emphasizes the basic ecological concept that everything is connected and (2) serves as a textbook version of interconnected Web links.
- Addition of comprehensive Review Questions at the end of each chapter.

Help Me Improve This Book Let me know how you think this book can be improved; if you find any errors, bias, or confusing explanations please send them to Jack Carey, Biology Publisher, Brooks/Cole, 10 Davis Drive, Belmont, CA 94002 (e-mail: jack.carey@brookscole.com). He will forward them to me. Most errors can be corrected in subsequent printings of this edition rather than waiting for a new edition.

Acknowledgments I wish to thank the many students and teachers who responded so favorably to the 4 previous editions of *Sustaining the Earth*, the 12 editions of *Living in the Environment*, and the 8 editions of *Environmental Science* and who corrected errors and offered many helpful suggestions for improvement. I am also deeply indebted to the more than 200 reviewers who pointed out errors and suggested many important improvements in these three books. Any errors and deficiencies left are mine.

The members of the talented production team, listed on the copyright page, have made vital contributions as well. My thanks also go to (1) copyeditor Carol Anne Peschke, (2) production editors Brooks Ellis and Hal Humphrey, (3) Eileen Mitchell, Michael Gutch, and other members of the staff of Electronic Publishing Services Inc. who have improved the design of this edition and made my life much easier, (4) Brooks/Cole's hard-working sales staff, (5) Pat Waldo and her talented colleagues, who develop multimedia associated with this book, and (6) Richard K. Clements for his excellent work on the *Instructor's Manual*.

My deepest thanks go to Jack Carey, biology publisher at Brooks/Cole, for his encouragement, help, 34 years of friendship, and superb reviewing system. It helps immensely to work with the best and most experienced editor in college textbook publishing.

I dedicate this book to the earth and to Kathleen Paul, my research assistant and fiancée.

G. Tyler Miller, Jr.

CONTENTS

1 Environmental Issues, Their Causes, and Sustainability 1

- 1-1 Living More Sustainably 1
Spotlight: *Cast of Players in the Environmental Drama* 2
- 1-2 Population Growth, Economic Growth, and Sustainable Economic Development 4
Spotlight: *Current Exponential Growth of the Human Population* 5
- 1-3 Resources 6
Connections: *Free-Access Resources and the Tragedy of the Commons* 8
- 1-4 Pollution 10
- 1-5 Environmental and Resource Problems: Causes and Connections 11
- 1-6 Is Our Present Course Sustainable? 13
Solutions: *Some Guidelines for Working with the Earth* 14

2 Science, Matter, Energy, and Ecology: Connections in Nature 17

- 2-1 Science and Environmental Science 17
- 2-2 Matter and Energy 19
- 2-3 Earth's Life-Support Systems: From Organisms to the Biosphere 25
Spotlight: *Have You Thanked the Insects Today?* 27
Connections: *Microbes: The Invisible Rulers of the Earth* 27
- 2-4 Connections: Roles of Species in Ecosystems 34
Spotlight: *Cockroaches: Nature's Ultimate Survivors* 35
Connections: *Why Are Amphibians Vanishing?* 37
Case Study: *Why Are Sharks Important Species?* 38
- 2-5 Connections: Food Webs and Energy Flow in Ecosystems 41
- 2-6 Connections: Matter Cycling in Ecosystems 45
- 2-7 Life on Land and in Water Environments 51
- 2-8 Population Dynamics, Evolution, and Biodiversity 61
- 2-9 Ecological Succession 68
Connections: *Ecological Surprises* 70
- 2-10 Human Impacts on Ecosystems: Learning from Nature 70

Solutions: *Principles of Sustainability: Learning from Nature* 71

3 The Human Population: Size and Distribution 76

- 3-1 Factors Affecting Human Population Size 76
- 3-2 Population Age Structure 80
- 3-3 Solutions: Influencing Population Size 82
Case Study: *Immigration in the United States* 83
- 3-4 Case Studies: Slowing Population Growth in India, China, and Thailand 87
- 3-5 Population Distribution: Urbanization and Urban Transportation Systems 89
Case Study: *Mexico City* 91
Spotlight: *The Urban Poor* 92
- 3-6 Urban Environmental and Resource Problems 94
Pro/Con: *Good and Bad News About Motor Vehicles* 95
Solutions: *Curitiba, Brazil* 97
- 3-7 Solutions: Making Urban Areas More Livable and Sustainable 97

4 Energy 102

- 4-1 Evaluating Energy Resources 102
- 4-2 Improving Energy Efficiency 105
Connections: *Using the Internet to Save Energy and Paper and Reduce Global Warming* 112
- 4-3 Using Solar Energy to Provide Heat and Electricity 112
- 4-4 The Solar-Hydrogen Revolution 122
Spotlight: *Producing Hydrogen from Green Algae Found in Pond Scum* 125
- 4-5 Geothermal Energy 125
- 4-6 Nonrenewable Fossil Fuels 126
Case Study: *The Exxon Valdez Oil Spill* 127
Pro/Con: *Should Oil and Gas Development Be Allowed in the Arctic National Wildlife Refuge?* 129
- 4-7 Nonrenewable Nuclear Energy 132
Case Study: *The Chernobyl Nuclear Power-Plant Accident* 136
Case Study: *Underground Storage of High-Level Radioactive Wastes in the United States* 137
- 4-8 Solutions: A Sustainable Energy Strategy 139

5 Sustaining Terrestrial and Aquatic Biodiversity: The Ecosystem Approach 143

- 5-1 Biodiversity and Conservation Biology 143
- 5-2 Public Lands in the United States 144
- 5-3 Managing and Sustaining Forests 146
Spotlight: *What Is the Economic Value of the Earth's Ecological Services?* 147
- 5-4 Forest Resources and Management in the United States 152
Solutions: *Certifying Sustainably Grown Timber* 153
Solutions: *How Can U.S. Federal Forest Management Be Improved?* 155
- 5-5 Tropical Deforestation and the Fuelwood Crisis 155
Solutions: *The Incredible Neem Tree* 156
Individuals Matter: *Kenya's Green Belt Movement* 160
Individuals Matter: *Ecological Restoration of a Tropical Dry Forest in Costa Rica* 161
- 5-6 Managing and Sustaining Rangelands 162
Spotlight: *Endangered Riparian Zones* 162
Individuals Matter: *The Eco-Rancher* 164
- 5-7 Managing and Sustaining National Parks 164
Case Study: *Who's Afraid of the Big Gray Wolf?* 166
- 5-8 Protecting and Managing Nature Reserves 167
Solutions: *The Nature Conservancy* 167
Solutions: *Biosphere Reserves* 170
Case Study: *The U.S. National Wilderness Preservation System* 171
- 5-9 Sustaining Aquatic Biodiversity 171

6 Sustaining Biodiversity: The Species Approach 175

- 6-1 Species Extinction 175
Case Study: *The Passenger Pigeon: Gone Forever* 178
Case Study: *Bats Are Getting a Bad Rap* 179
- 6-2 Why Preserve Species? 179
Spotlight: *Is There Really an Extinction Crisis?* 180
Connections: *Biophilia* 182
- 6-3 Causes of Depletion and Premature Extinction of Wild Species 182
Case Study: *The Plight of Migrating Birds* 184
Connections: *Deliberate Introduction of the Kudzu Vine* 186
Case Study: *The Termite from Hell* 187
- 6-4 Solutions: Protecting Wild Species from Depletion and Extinction 190
Spotlight: *Accomplishments of the Endangered Species Act* 192

- 6-5 Wildlife Management 194
- 6-6 Fishery Management 195
Connections: *What Should Be Done About Snow Geese?* 196
- 6-7 Case Study: Should Commercial Whaling Be Resumed? 197
Spotlight: *Near Extinction of the Blue Whale* 198

7 Biodiversity: Sustaining Soils and Producing Food 201

- 7-1 Soil and Soil Erosion 201
Case Study: *The Dust Bowl* 207
- 7-2 Solutions: Soil Conservation 208
Case Study: *Slowing Soil Erosion in the United States* 211
- 7-3 How Is Food Produced? 211
Individuals Matter: *Perennial Crops on the Kansas Prairie* 215
- 7-4 Food Production, Nutrition, and Environmental Effects 215
Solutions: *Saving Children* 218
- 7-5 Solutions to World Food Problems 219
Case Study: *Can China's Population Be Fed?* 220
Spotlight: *Shrinking the World's Genetic Plant Library* 222
Connections: *Some Environmental Consequences of Meat Production* 225
Spotlight: *How Useful Is International Food Aid?* 227
- 7-6 Protecting Food Resources: Pesticides and Pest Control 227
Individuals Matter: *Rachel Carson* 229
Spotlight: *How Effective Have Synthetic Pesticides Been in Reducing Crop Losses?* 231
Connections: *What Goes Around Can Come Around* 232
- 7-7 Solutions: Sustainable Agriculture 234

8 Risk, Toxicology, and Human Health 238

- 8-1 Risks and Hazards 238
- 8-2 Toxicology 238
Spotlight: *What Is the Biggest Killer?* 239
- 8-3 Chemical Hazards 241
Connections: *Are Hormone Disrupters and Mimics a Health Threat?* 243
- 8-4 Biological Hazards: Disease in Developed and Developing Countries 243
Spotlight: *Are We Losing the War Against Infectious Bacteria?* 244
- 8-5 Risk Analysis 247
Solutions: *Improving Health Care in Developing Countries* 247

9 Climate Change, Ozone Depletion, and Air Pollution 254

- 9-1 Atmosphere, Weather, and Climate 254
- 9-2 Global Warming: How Serious Is the Threat? 258
- 9-3 Factors Affecting Changes in the Earth's Average Temperature 262
- 9-4 Some Possible Effects of a Warmer World 265
- 9-5 Solutions: Dealing with the Threat of Climate Change 266
 - Solutions: *Energy Efficiency to the Rescue* 267
- 9-6 Ozone Depletion in the Stratosphere 269
 - Connections: *The Cancer You Are Most Likely to Get* 272
 - Individuals Matter: *Ray Turner and His Refrigerator* 273
- 9-7 Solutions: Protecting the Ozone Layer 273
- 9-8 Types and Sources of Outdoor and Indoor Air Pollution 274
- 9-9 Effects of Air Pollution on Living Organisms and Materials 285
- 9-10 Solutions: Preventing and Reducing Air Pollution 286

10 Water Resources and Water Pollution 293

- 10-1 Water's Importance and Unique Properties 293
- 10-2 Supply, Renewal, and Use of Water Resources 293
- 10-3 Water Resource Problems: Too Little Water and Too Much Water 297
 - Connections: *Living Dangerously on Floodplains in Bangladesh* 300
- 10-4 Solutions: Supplying More Water 300
 - Case Study: *The Aral Sea Water Transfer Disaster* 302
 - Case Study: *Mining Groundwater: The Shrinking Ogallala Aquifer* 305
- 10-5 Solutions: Wasting Less Water 306
 - Solutions: *The Promise of Drip Irrigation* 309
 - Spotlight: *Running Out of Water in Las Vegas, Nevada* 310
- 10-6 Types, Effects, and Sources of Water Pollutants 310
- 10-7 Pollution of Freshwater Streams, Lakes, and Aquifers 312
 - Individuals Matter: *Tracking Down the Pfiesteria Cell from Hell* 316
- 10-8 Ocean Pollution 318
- 10-9 Solutions: Preventing and Reducing Surface Water Pollution 322
 - Case Study: *Hurricanes, Hog Farms, and Water Pollution in Eastern North Carolina* 322

- Solutions: *Using Wetlands to Treat Sewage* 326
- 10-10 Solutions: Achieving a More Sustainable Water Future 327

11 Solid and Hazardous Waste 331

- 11-1 Wasting Resources 331
- 11-2 Producing Less Waste and Pollution 332
 - Solutions: *Doing More with Less: Increasing Resource Productivity* 334
- 11-3 Solutions: Cleaner Production and Selling Services Instead of Things 335
 - Individuals Matter: *Ray Anderson* 336
- 11-4 Reuse 337
 - Solutions: *What Kind of Grocery Bags Should We Use?* 337
- 11-5 Recycling 338
 - Solutions: *Using Composting to Recycle Biodegradable Wastes* 340
 - Case Study: *Recycling Aluminum* 341
 - Pro/Con: *Does Recycling Make Economic Sense?* 342
- 11-6 Detoxifying, Burning, Burying, and Exporting Wastes 342
- 11-7 Case Studies: Lead and Dioxins 347
- 11-8 Hazardous-Waste Regulation in the United States 349
 - Spotlight: *Using Honeybees to Detect Toxic Pollutants* 349
 - Solutions: *How Can the Superfund Law Be Improved?* 350
- 11-9 Solutions: Achieving a Low-Waste Society 351

12 Environmental Economics, Politics, and Worldviews 354

- 12-1 Economic Systems and Environmental Problems 354
- 12-2 Solutions: Using Economics to Improve Environmental Quality 359
 - Solutions: *Shifting the Tax Burden from Wages and Profits to Pollution and Waste* 363
- 12-3 Reducing Poverty to Improve Environmental Quality and Human Well-Being 364
 - Solutions: *Microloans to the Poor* 365
- 12-4 Making the Transition to Environmentally Sustainable Economies 365
 - Connections: *Jobs and the Environment* 366
- 12-5 Politics and Environmental Policy 367
 - Individuals Matter: *Environmental Careers* 369
 - Solutions: *Election Finance Reform* 372
- 12-6 Global Environmental Policy 373
 - Individuals Matter: *Environmental Action on Campuses* 374
- 12-7 Environmental Worldviews: Clashing Values and Cultures 375

Case Study: *Biosphere 2: A Lesson in Humility* 378
Connections: *Why Should We Care About Future Generations?* 380
Individuals Matter: *Mindquake: Evaluating One's Environmental Worldview* 381
Connections: *Learning from the Earth* 382

- 2 Major Events in U.S. Environmental History A2

- 3 Major U.S. Resource Conservation and Environmental Legislation A6
- 4 Individuals Matter: What Can You Do? A7

Glossary G1

Index I1

1 ENVIRONMENTAL ISSUES, THEIR CAUSES, AND SUSTAINABILITY

Alone in space, alone in its life-supporting systems, powered by inconceivable energies, mediating them to us through the most delicate adjustments, wayward, unlikely, unpredictable, but nourishing, enlivening, and enriching in the largest degree—is this not a precious home for all of us? Is it not worth our love?

BARBARA WARD AND RENÉ DUBOS

1-1 LIVING MORE SUSTAINABLY

What Is the Difference Between Environment, Ecology, and Environmental Science? **Environment** is everything that affects a living organism (any unique form of life). **Ecology** is a biological science that studies the relationships between living organisms and their environment.

This textbook is an introduction to **environmental science**. It is an interdisciplinary science that uses concepts and information from *natural sciences* such as ecology, biology, chemistry, and geology and *social sciences* such as economics, politics, and ethics to (1) help us understand how the earth works, (2) learn how we are affecting the earth's life-support systems (environment) for us and other forms of life, and (3) propose and eval-

uate solutions to the environmental problems we face. Many different groups of people are concerned about environmental issues (Spotlight, p. 2).

What Is Exponential Growth? Once there were two kings from Babylon who enjoyed playing chess, with the winner claiming a prize from the loser. After one match, the winning king asked the loser to pay him by placing one grain of wheat on the first square of the chessboard, two on the second, four on the third, and so on. The number of grains was to double each time until all 64 squares were filled.

The losing king, thinking he was getting off easy, agreed with delight. It was the biggest mistake he ever made. He bankrupted his kingdom and still could not produce the incredibly large number of grains of wheat he had promised. In fact, it's probably more than all the wheat that has ever been harvested!

This is an example of **exponential growth**, in which a quantity increases by a fixed percentage of the whole in a given time. As the losing king learned, exponential growth is deceptive. It starts off slowly, but after only a few doublings it grows to enormous numbers because each doubling is more than the total of all earlier growth.

Any quantity growing by a fixed percentage, even as small as 0.001% or 0.1%, is undergoing exponential growth. If this growth continues, the quantity will experience extraordinary growth as its base of growth doubles again and again. If plotted on a graph, continuing exponential growth of something such as the size of the human population eventually yields a graph shaped somewhat like the letter J (Figure 1-1).

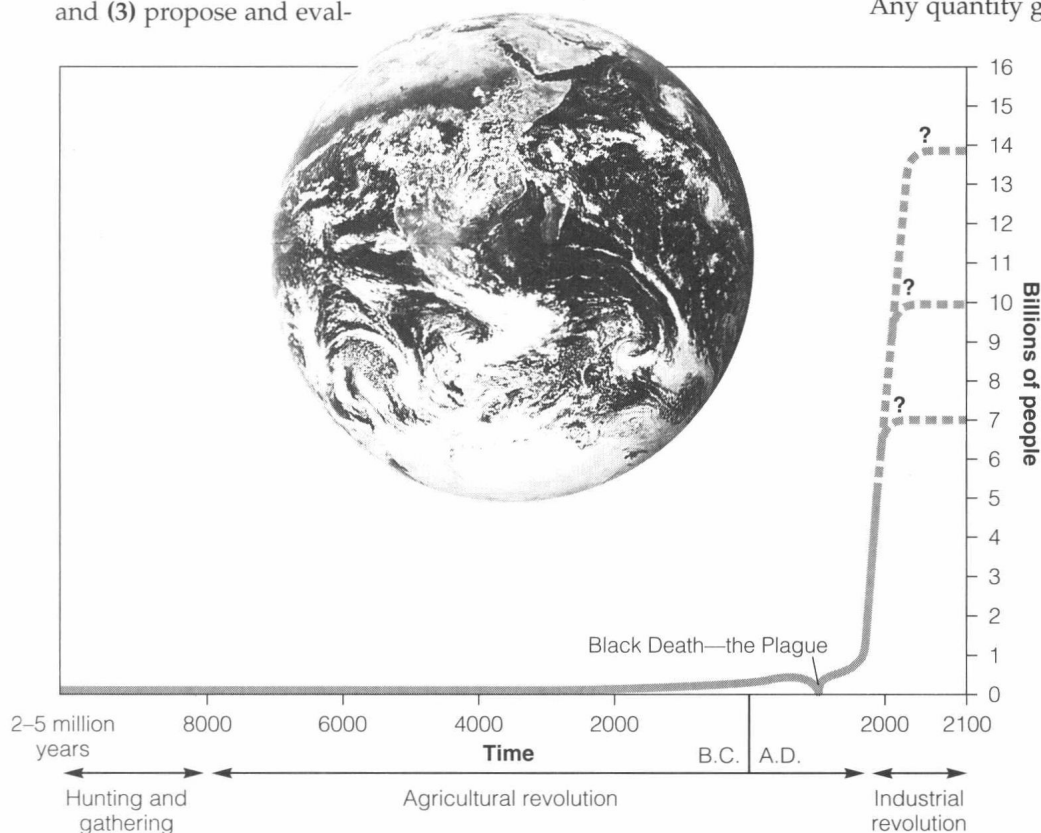

Figure 1-1 The J-shaped curve of past exponential world population growth, with projections beyond 2100. Notice that exponential growth starts off slowly, but as time passes the curve becomes increasingly steep. The current world population of 6.1 billion people is projected to grow to 8–15 billion people during the twenty-first century. (This figure is not to scale.) (Data from World Bank and United Nations; photo courtesy of NASA)

Cast of Players in the Environmental Drama

The cast of major characters you will encounter in this book include the following:

- **Ecologists**, who are biological scientists studying relationships between living organisms and their environment.
- **Environmental scientists**, who use information from the physical sciences and social sciences to (1) understand how the earth works, (2) learn how humans interact with the earth, and (3) develop solutions to environmental problems.
- **Conservation biologists**, who in the 1970s created a multidisciplinary

science to (1) investigate human impacts on the diversity of life found on the earth (biodiversity) and (2) develop practical plans for preserving such biodiversity.

- **Environmentalists**, who are concerned about the impact of people on environmental quality and believe that some human actions are degrading parts of the earth's life-support systems for humans and many other forms of life. Some of their beliefs and proposals for dealing with environmental problems are based on scientific information and concepts and some are based on their social and ethical environmental beliefs (environmental worldviews). Environmentalists

are a broad group of people from different economic groups (rich, middle-class, poor) and with different political persuasions (conservative and liberal).

- **Preservationists**, concerned primarily with setting aside or protecting undisturbed natural areas from harmful human activities.
- **Conservationists**, concerned with using natural areas and wildlife in ways that sustain them for current and future generations of humans and other forms of life.

Critical Thinking

Which, if any, of these groups do you most identify with? Why?

Here is another example. Fold a piece of paper in half to double its thickness. If you could do this 42 times, the stack would reach from the earth to the moon, 386,400 kilometers (240,000 miles) away. If you could double it 50 times, the folded paper would almost reach the sun, 149 million kilometers (93 million miles) away!

The environmental issues we face include (1) *population growth*, (2) *increasing resource use*, (3) *destruction and degradation of wildlife habitats*, (4) *premature extinction of plants and animals*, (5) *poverty*, and (6) *pollution*. All these issues are interconnected and are growing exponentially.

For example, world population has more than doubled in 49 years, from 2.5 billion in 1950 to 6.1 billion in 2000. Unless death rates rise sharply, it may reach 8 billion by 2028, 9 billion by 2054, and 10–15 billion by 2100 (Figure 1-1). Global economic output, much of it environmentally damaging, is a rough measure of resource use. It has increased almost fivefold since 1950.

There is an abundance of *bad environmental news*. According to leading ecologists and environmental scientists, (1) forests are shrinking, (2) grasslands are deteriorating from overgrazing by livestock, (3) soils are eroding, (4) plant and animal species are disappearing, (5) fisheries are collapsing, (6) rivers are running dry, (7) some countries are squabbling over access to shared but limited water supplies, (8) underground water is pumped from wells faster than it can be replenished, (9) wetlands are disappearing, (10) coral reefs are dying, (11) temperatures are rising, and (12) glaciers are melting. Recent studies by researchers at Conservation

International suggest that roughly 73% of the earth's habitable land surface (that which is not bare rock, ice, or drifting sand) has been partially or heavily disturbed by human activities.

During this century, the earth's climate may become warm enough to (1) disrupt agricultural productivity, (2) alter water distribution, (3) drive countless species to extinction, and (4) cause economic chaos because of the release of certain gases into the lower atmosphere from burning fossil fuels and the destruction of forests. Extracting and burning fossil fuels (oil, coal, and natural gas) also pollutes the air and water and disrupts the land. Other chemicals we add to the air drift into the upper atmosphere and deplete a gas (ozone) that filters out much of the sun's harmful ultraviolet radiation. Toxic wastes from factories and mines poison the air, water, and soil. Agricultural pesticides contaminate some of our drinking water and food.

There is also some exciting *good news*. Mainly because of improved sanitation and medical advances, average human life expectancy doubled and global infant mortality dropped by almost two-thirds during the 20th century. Since the 1960s global food production has outpaced population growth, thanks mostly to new high-yield forms of agriculture.

Because of improved mining technology, there have been significant increases in proven deposits of almost all the earth's fossil fuel and mineral resources since 1950. Since 1970 air and water pollution levels in most industrialized countries have dropped because of new pollution control laws and technologies. Recently, industrial

nations have developed international treaties to phase out production of chemicals that deplete ozone in the upper atmosphere.

What Keeps Us Alive? Our existence, lifestyles, and economies depend completely on the sun and the earth, a blue and white island in the black void of space. To economists *capital* is wealth used to sustain a business and to generate more wealth. By analogy, we can think of energy from the sun as **solar capital** and the planet's air, water, soil, wildlife, minerals, and natural purification, recycling, and pest control processes as **natural resources** or **natural capital** (Figure 1-2).

Solar energy is defined broadly to include direct sunlight and indirect forms of solar energy such as (1) wind power, (2) hydropower (energy from flowing water), and (3) biomass (direct solar energy converted to chemical energy stored in biological sources of energy such as wood).

What Is an Environmentally Sustainable Society?

To survive and maintain good health, all forms of life must have enough food, clean air, clean water, and shelter to meet their *basic needs*. Additional needs for humans include respectable and safe work, health care, recreation, cultural opportunities, education, and freedom from physical danger. Can you add any other basic needs that you have?

An **environmentally sustainable society** satisfies the basic needs of its people without depleting or degrading its natural resources and thereby preventing current and future generations of humans and other species from meeting their basic needs. *Living sustainably* means living off the natural income replenished by soils, plants, air, and water and not depleting the natural capital (Figure 1-2) that supplies this income.

For example, imagine that you inherit \$1 million. Invest this capital at 10% interest per year and you will have a sustainable annual income of \$100,000 without depleting your capital. If you spend \$200,000 a year, your \$1 million will be gone early in the 7th year; even if you spend only \$110,000 a year, you will be bankrupt early in the 18th year.

The lesson here is a very old one: *Don't kill the goose that lays the golden egg, or protect your capital*. Deplete your capital, and you move from a sustainable to an unsustainable lifestyle.

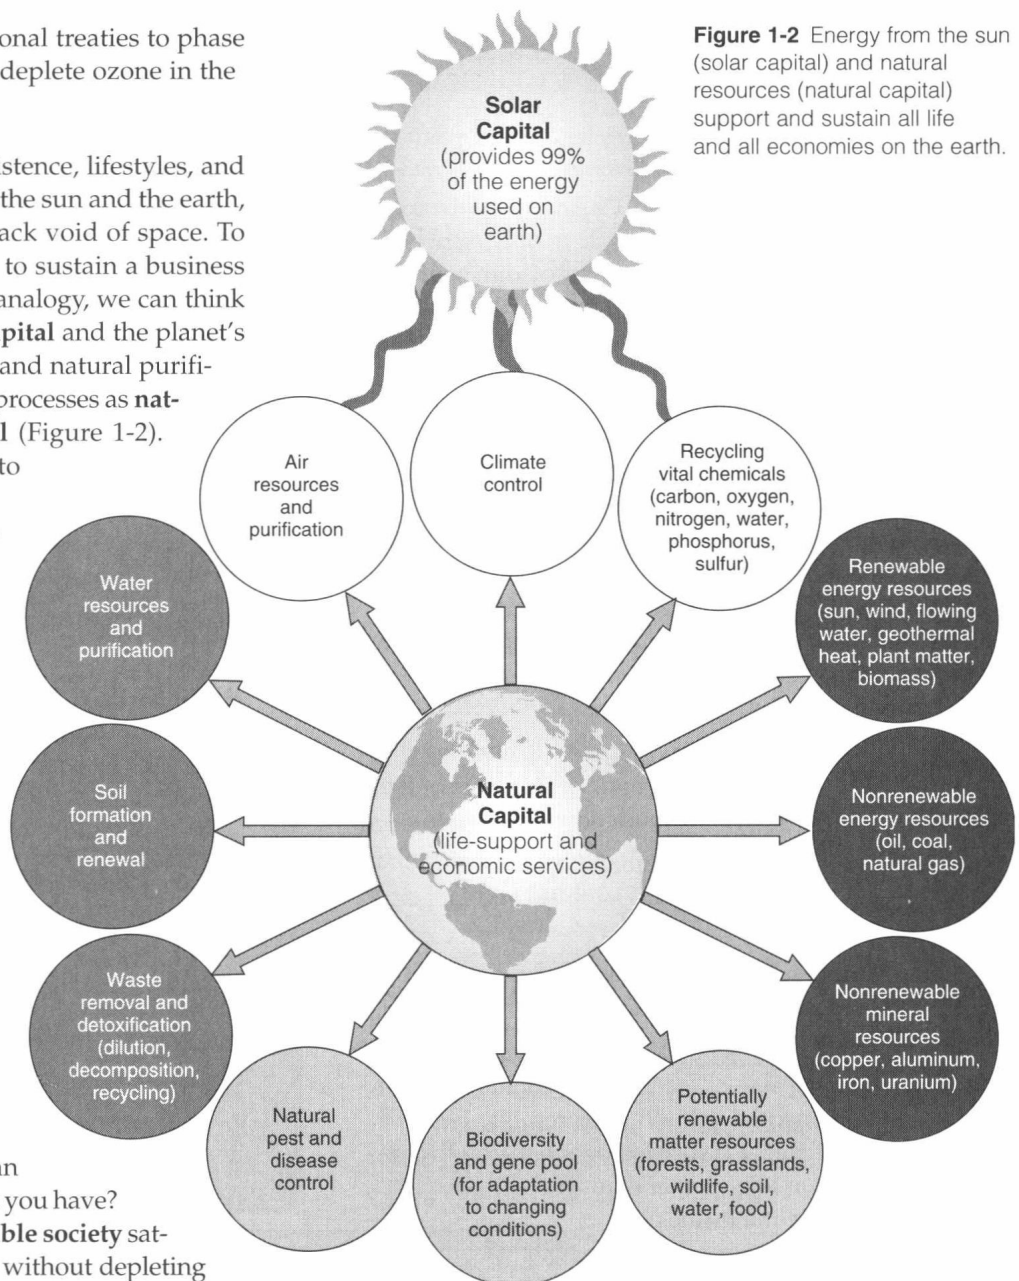

Figure 1-2 Energy from the sun (solar capital) and natural resources (natural capital) support and sustain all life and all economies on the earth.

The same lesson applies to natural capital (Figure 1-2). Environmentalists and many leading scientists believe that we are living unsustainably by depleting and degrading the earth's natural capital at an accelerating rate as our population (Figure 1-1) and demands on the earth's resources and life-sustaining processes increase exponentially.

Other analysts do not believe that we are living unsustainably. They contend (1) that environmentalists have exaggerated the seriousness of population and environmental problems and (2) that any population, resource, and environmental problems we face can be overcome by human ingenuity and technological advances.

1-2 POPULATION GROWTH, ECONOMIC GROWTH, AND SUSTAINABLE ECONOMIC DEVELOPMENT

How Rapidly Is the Human Population Growing? Evidence from fossils and studies of ancient cultures suggests that the current form of our species, *Homo sapiens sapiens*, has walked the earth for only about 60,000 years (some recent evidence suggests 90,000 to 176,000 years), an instant in the planet's estimated 4.6-billion-year existence.

Until about 12,000 years ago, we were mostly hunter-gatherers who typically moved as needed to find enough food for survival. Since then, there have been three major cultural changes: (1) the *agricultural revolution* (which began 10,000–12,000 years ago), (2) the *industrial revolution* (which began about 275 years ago), and (3) the *information and globalization revolution* (which began about 50 years ago).

These major cultural changes have

- Given us much more energy (Figure 1-3) and new technologies with which to alter and control more of the planet to meet our basic needs and increasing wants
- Allowed expansion of the human population, mostly because of increased food supplies and longer life spans (Figure 1-4)
- Increased our environmental impact because of increased resource use, pollution, and environmental degradation

The increasing size of the human population is an example of exponential growth (Figures 1-1, 1-4, and 1-5 and Spotlight, right). If such exponential growth continues (even at a low percentage of annual growth), eventually the population growth curve rounds a bend and heads almost straight up, creating a *J-shaped curve* (Figure 1-1). The main reason for the rapid growth of the human population over the past 100 years has been a much greater drop in death rates (mostly because of increases in food supply and better health and sanitation) than in birth rates.

Figure 1-4 Technological innovations have led to greater human control over the rest of nature and an expanding human population. Dashed lines represent three alternative population futures: (1) continued growth (top), (2) stabilization (middle), and (3) a crash and stabilization at a much lower level.

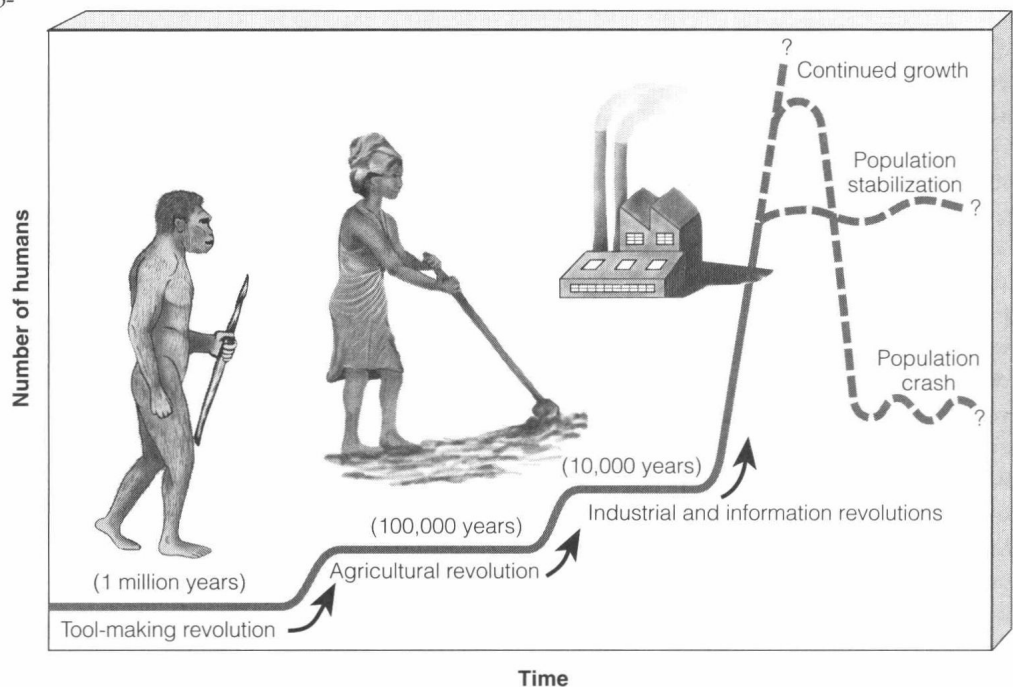

Figure 1-3 Average direct and indirect daily energy use per person at various stages of human cultural development. A typical citizen in a modern industrial society uses 65 to 130 times as much energy per day as a hunter-gatherer.

What Is Economic Growth? Almost all countries seek **economic growth**: an increase in their capacity to provide goods and services for people's final use. This increase is accomplished by population growth (more consumers and producers), more consumption per person, or both.

Economic growth usually is measured by an increase in several indicators:

- **Gross national product (GNP):** the market value in current dollars of all goods and services produced *within* and *outside* a country by the country's businesses for final use during a year
- **Gross domestic product (GDP):** the market value in current dollars of all goods and services produced

Current Exponential Growth of the Human Population

SPOTLIGHT

The world's population is growing exponentially at a rate of about 1.35% per year. The relentless ticking of

this population clock means that in 2000 the world's population of 6.1 billion grew by 82 million people ($6.1 \text{ billion} \times 0.0135 = 82 \text{ million}$), an average increase of 225,000 people a day, or 9,400 an hour.

At this 1.35% annual rate of exponential growth, it takes only about

- 5 days to add the number of Americans killed in all U.S. wars

- 2 months to add as many people as live in the Los Angeles basin
- 1.6 years to add the 129 million people killed in all wars fought in the past 200 years
- 3.4 years to add 281 million people (the population of the United States in 2000)
- 15 years to add 1.26 billion people (the population of China, the world's most populous country, in 2000)

How much is a billion? If you could live for a billion minutes, you would be 1,902 years old. To travel 1.6 billion kilometers (1 billion

miles), you would have to circle the earth about 40,000 times.

Critical Thinking

Some economists argue that population growth is good because it provides more workers, consumers, and problem solvers to keep the global economy growing. Environmentalists argue that population growth threatens economies and the earth's life-support systems through increased pollution and environmental degradation. What is your position? Why?

Figure 1-5 World population milestones. (Data from United Nations Population Division, *World Population Prospects*, 1998)

World Population Reached	
1 billion	in 1804
2 billion	in 1927 (123 years later)
3 billion	in 1960 (33 years later)
4 billion	in 1974 (14 years later)
5 billion	in 1987 (13 years later)
6 billion	in 1999 (12 years later)
World Population May Reach	
7 billion	in 2013 (14 years later)
8 billion	in 2028 (15 years later)
9 billion	in 2054 (26 years later)

within a country for final use during a year

- **Per capita GNP:** the GNP divided by the total population. It gives the average slice of the economic pie per person.

Economic development is the improvement of living standards by economic growth. The United Nations classifies the world's countries as economically developed or developing based primarily on their degree of industrialization and their per capita GNP.

The **developed countries** include the United States, Canada, Japan, Australia, New Zealand, and all the countries of Europe. Most are highly industrialized and have high average per capita GNPs (above \$10,000 per year, except for industrialized countries in eastern Europe and some in northern and southern Europe). These countries, with 1.2 billion people (20% of the world's population in 2000), (1) have about 85% of the world's wealth and income, (2) use about 88% of its natural resources, and (3) generate about 75% of its pollution and waste.

All other nations are classified as **developing countries**, most of them in Africa, Asia, and Latin America. Their 4.9 billion people (80% of the world's population

in 2000) (1) have only about 15% of the wealth and income and (2) use only about 12% of the world's natural resources. Some are *middle-income, moderately developed countries* with average per capita GNPs of \$1,000 to \$10,000 per year. Examples are South Africa, Mexico, Argentina, Brazil, Saudi Arabia, Malaysia, and Thailand. Others are *low-income countries* with per capita GNPs less than \$1,000 per year. Examples include India, China, Bangladesh, Pakistan, Vietnam, Nicaragua, Haiti, Bolivia, and most of the countries in western, eastern, and central Africa.

More than 95% of the projected increase in the world's population is expected to take place in developing countries (Figure 1-6), where 1 million people are

Figure 1-6 Past and projected population size for developed countries, developing countries, and the world, 1950–2120. More than 95% of the addition of 3.6 billion people between 1990 and 2030 is projected to occur in developing countries. (Data from United Nations)

added every 5 days. The primary reason for such rapid population growth in developing countries (1.7% compared to 0.1% in developed countries) is the *large percentage of people who are under age 15* (34% compared to 19% in developed countries in 2000). As these young people move into their prime reproductive years over the next several decades, they will fuel rapid population growth.

What Is Environmentally Sustainable Economic Development? Some analysts have called for a shift from emphasis on traditional economic development fueled by economic growth of essentially any type to emphasis on **environmentally sustainable economic development**. This type of development (1) *encourages* environmentally sustainable forms of economic growth that meet the basic needs of the current generations of humans and other species without preventing future generations of humans and other species from meeting their basic needs and (2) *discourages* environmentally harmful and unsustainable forms of economic growth. In other words, environmentally sustainable economic development is the economic component of *environmentally sustainable societies*.

What Is the Wealth Gap? Since 1960, and especially since 1980, the gap between the per capita GNP of the rich, middle income, and poor has widened (Figure 1-7). According to the United Nations, about 1.2 billion people—one person in five—are hungry or malnourished and lack access to clean water, decent housing, and adequate health care. One of every three people lacks enough fuel to keep warm and to cook food and does not have access to electricity. About two-thirds of humanity lacks sanitary toilets and one of every four adults (1.3 billion people) is illiterate.

Daily life is a harsh struggle for the estimated one of every two people on the earth who try to survive on an income of \$1–3 per day. Many poor parents have many children as a form of economic security to (1) help them grow food, (2) gather fuel (mostly wood and dung), (3) haul drinking water, (4) tend livestock, (5) work, (6) beg in the streets, and (7) help them survive in their old age (typically their 50s or 60s). Poor people

- May deplete and degrade local forests, soil, grasslands, wildlife, and water supplies for short-term survival even though they know it may lead to disaster in the long run
- Often have to live in areas with the highest levels of air and water pollution and with the greatest risk of natural disasters such as floods, earthquakes, hurricanes, and volcanic eruptions
- Spend an average of (1) 4–6 hours per day searching for and carrying fuelwood and (2) 4–6 hours per week drawing and carrying water

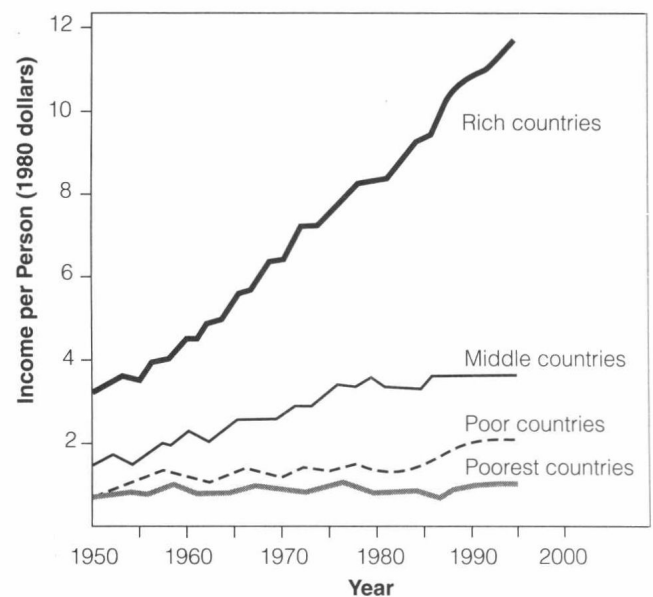

Figure 1-7 The wealth gap: changes in the distribution of global per capita GNP in high-income, middle-income, low-income, and very low-income countries, 1950–96. Instead of trickling down, most of the income from economic growth has flowed up, with the situation worsening since 1980. More than 1 billion people survive on less than \$1 a day. (Data from United Nations)

- Must take jobs (if they can find them) that subject them to unhealthy and unsafe working conditions at very low pay

According to the World Health Organization (WHO), each year, at least 10 million of the desperately poor die prematurely of (1) malnutrition (lack of protein and other nutrients needed for good health), (2) increased susceptibility to infectious diseases because of their weakened condition from malnutrition, and (3) infectious diseases from drinking contaminated water. *This premature death of about 27,400 human beings per day is equivalent to 69 jumbo jet planes, each carrying 400 passengers, crashing every day with no survivors. Half of those dying are children under age 5.*

Mostly because of the high use of natural resources in developed countries, the environmental impact or *ecological footprint* per person in developed countries is large compared with that in developing countries (Figure 1-8).

1-3 RESOURCES

What Is a Resource? From a human standpoint, a **resource** is anything obtained from the environment to meet human needs and wants. Examples include food, water, shelter, manufactured goods, trans-

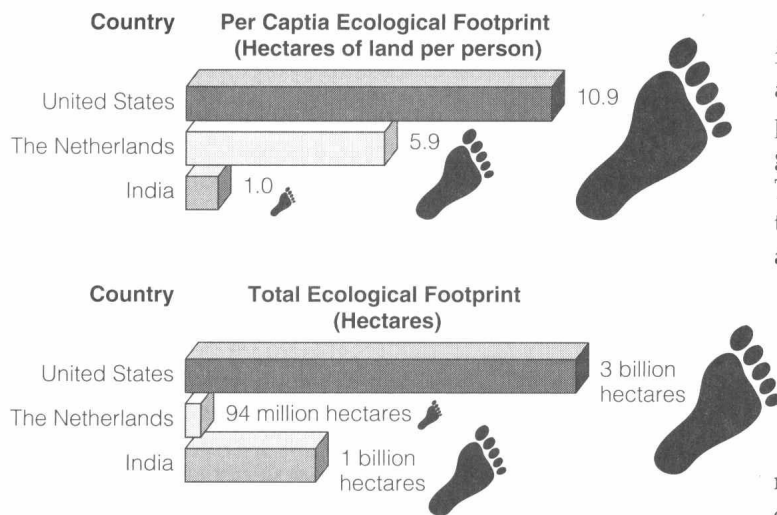

Figure 1-8 Relative ecological footprints of the United States, the Netherlands, and India. An *ecological footprint* is the amount of land needed to produce the resources needed by an average person in a country. The total ecological footprint for the 16 million people living in the Netherlands is 15 times the country's area. Indeed, it would take the land area of about three earths if all the world's 6.1 billion people consumed the same amount of resources as is consumed by the 281 million people in the United States.

portation, communication, and recreation. On our short human time scale, we classify the material resources we get from the environment as (1) *perpetual*, (2) *renewable*, or (3) *nonrenewable* (Figure 1-9).

Some resources, such as solar energy, fresh air, wind, fresh surface water, fertile soil, and wild edible plants, are directly available for use. Other resources, such as petroleum (oil), iron, groundwater (water found underground), and modern crops, are not directly available. They become useful to us only with some effort and technological ingenuity. For example, petroleum was a mysterious fluid until we learned how to find, extract, and convert (refine) it into gasoline, heating oil, and other products that could be sold at affordable prices.

What Are Perpetual and Renewable Resources? Solar energy is called a **perpetual resource** because on a human time scale it is renewed continuously. It is expected to last at least 6 billion years as the sun completes its life cycle.

On a human time scale, a **renewable resource** can be replenished fairly rapidly (hours to several decades) through natural processes as long as it is not used up faster than it is replaced. These resources are *flow resources* that pass through plants, economies, and other systems. They are endlessly renewable but only at the rate at which nature provides them. Examples are (1) forests, (2) grasslands, (3) wild animals, (4) fresh water, (5) fresh air, and (6) fertile soil.

However, renewable resources can be depleted or degraded. The highest rate at which a renewable resource can be used *indefinitely* without reducing its available supply is called **sustainable yield**.

If we exceed a resource's natural replacement rate, the available supply begins to shrink, a process known as **environmental degradation**. Examples of such degradation include (1) urbanization of productive land, (2) waterlogging and salt buildup in soil, (3) excessive topsoil erosion, (4) deforestation, (5) groundwater depletion, (6) overgrazing of grasslands by livestock, (7) reduction in the earth's forms of wildlife (biodiversity) by elimination of habitats and species, and (8) pollution.

Such forms of environmental degradation can change usable, renewable resources into nonrenewable or unusable resources. A major cause of environmental degradation of renewable resources is a phenomenon known as the *tragedy of the commons* (Connections, p. 8).

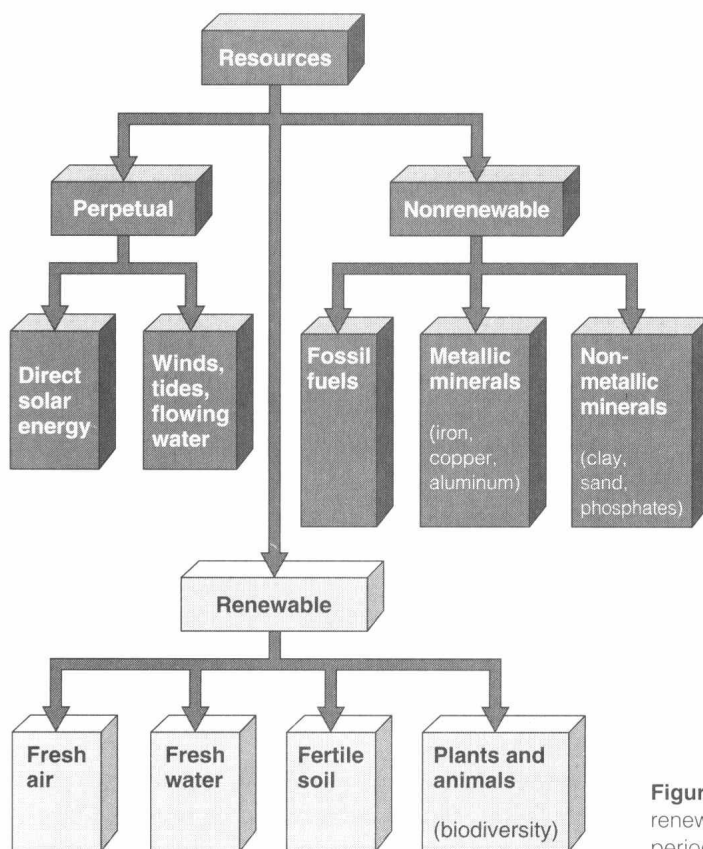

Figure 1-9 Major types of material resources. This scheme is not fixed; renewable resources can become nonrenewable if used for a prolonged period at a faster rate than they are renewed by natural processes.

CONNECTIONS

Free-Access Resources and the Tragedy of the Commons

One cause of environmental degradation is the overuse of **common-property** or **free-access**

resources. Such resources are owned by no one (or jointly by everyone in a country or area) but are available to all users at little or no charge.

Examples include (1) clean air, (2) the open ocean and its fish, (3) migratory birds, (4) wildlife species, (5) publicly owned lands (such as national forests, national parks, and wildlife refuges), (6) gases of the lower atmosphere, and (7) space.

In 1968, biologist Garrett Hardin called the degradation of renewable free-access resources the **tragedy of the commons**. It happens because each user reasons, "If I do not use this resource, someone else will. The little bit I use or pollute is not enough to matter, and such resources are renewable."

With only a few users, this logic works. However, the cumulative effect of many people trying to exploit a free-access resource eventually exhausts or ruins it. Then no one can benefit from it, and therein lies the tragedy.

Two solutions to this problem are to

- *Use free-access resources at rates well below their estimated sustainable yields or overload limits by reducing population, regulating access, or both.* This prevention approach is rarely used because (1) it entails establishing and enforcing regulations that restrict resource use or population growth, and (2) it is difficult and expensive to determine the sustainable yield of a forest, grassland, or animal population because such yields vary with weather, climate, and unpredictable biological factors.
- *Convert free-access resources to private ownership.* The reasoning is that owners of land or some other resource have a strong incen-

tive to protect their investment. However, this approach is not practical for global common resources (such as the atmosphere, the open ocean, most wildlife species, and migratory birds) that cannot be divided up and converted to private property.

Experience shows that there is another possibility. Just because a resource is easily available to a community does not always mean that people have free and unregulated access to that resource. There are many examples in which communities have established a set of rules and traditions to regulate and share their access to a common-property resource such as fisheries, grazing lands, and forests.

Critical Thinking

Give three examples of how you cause environmental degradation as a result of the tragedy of the commons. How should we deal with this problem? Explain.

What Are Nonrenewable Resources? Resources that exist in a fixed quantity or stock in the earth's crust are called **nonrenewable resources**. On a time scale of millions to billions of years, geological processes can renew such resources. However, on the much shorter human time scale of hundreds to thousands of years, these resources can be depleted much faster than they are formed.

These exhaustible resources include (1) *energy resources* (such as coal, oil, and natural gas, which cannot be recycled), (2) *metallic mineral resources* (such as iron, copper, and aluminum, which can be recycled), and (3) *nonmetallic mineral resources* (such as salt, clay, sand, and phosphates, which usually are difficult or too costly to recycle).

A **mineral** is any hard, usually crystalline material that is formed naturally. We know how to find and extract more than 100 nonrenewable minerals from the earth's crust. We convert these raw materials into many everyday items and then we discard, reuse, or recycle them.

We never completely exhaust a nonrenewable mineral resource, but such a resource becomes *economically depleted* when the costs of extracting and using what is

left exceed its economic value. At that point, we have six choices: (1) try to find more, (2) recycle or reuse existing supplies (except for nonrenewable energy resources, which cannot be recycled or reused), (3) waste less, (4) use less, (5) try to develop a substitute, or (6) wait millions of years for more to be produced.

Some nonrenewable material resources, such as copper and aluminum, can be recycled or reused to extend supplies. **Recycling** involves collecting and reprocessing a resource into new products. For example, glass bottles can be crushed and melted to make new bottles or other glass items. **Reuse** involves using a resource over and over in the same form. For example, glass bottles can be collected, washed, and refilled many times.

Recycling nonrenewable metallic resources takes much less energy, water, and other resources and produces much less pollution and environmental degradation than exploiting virgin metallic resources. Reusing such resources takes even less energy than other resources and produces less pollution and environmental degradation than recycling.

Nonrenewable energy resources, such as coal, oil, and natural gas, cannot be recycled or reused. Once burned, the useful energy in these fossil fuels is
