内 容 简 介

本书重点介绍无线系统接收机设计中涉及到的信号检测和处理技术。本书主要介绍了盲多用户检测、组盲多用户检测、非高斯信道中的鲁棒多用户检测、空-时多用户检测、Turbo 多用户检测、窄带干扰抑制、Monte Carlo Bayesian 信号处理、衰落信道的信号处理、编码 OFDM 系统的信号处理等方面的内容。

本书可用做通信与电子、信息与信号处理等专业的高年级本科生、研究生的教材,也可作为相关人员的参考书。

PREFACE

Wireless communications, together with its applications and underlying technologies, is among today's most active areas of technology development. The very rapid pace of improvements in both custom and programmable integrated circuits for signal processing applications has led to the justifiable view of advanced signal processing as a key enabler of the aggressively escalating capacity demands of emerging wireless systems. Consequently, there has been a tremendous and very widespread effort on the part of the research community to develop novel signal processing techniques that can fulfill this promise. The published literature in this area has grown explosively in recent years, and it has become quite difficult to synthesize the many developments described in this literature. The purpose of this book is to present, in one place and in a unified framework, a number of key recent contributions in this field. Even though these contributions come primarily from the research community, the focus of this presentation is on the development, analysis, and understanding of explicit algorithms for performing advanced processing tasks arising in receiver design for emerging wireless systems.

Although this book is largely self-contained, it is written principally for designers, researchers, and graduate students with some prior exposure to wireless communication systems. Knowledge of the field at the level of Theodore Rappaport's book, *Wireless Communications: Principles and Practice* [405], for example, would be quite useful to the reader of this book, as would some exposure to digital communications at the level of John Proakis's book, *Digital Communications* [396].

Acknowledgments

The authors would like to thank the Army Research Laboratory, the National Science Foundation, the New Jersey Commission on Science and Technology, and the Office of Naval Research for their support of much of the research described in this book.

出版说明

近年来,通信与信息科技发展之快和应用之广,大大超出了人们的预料和专家的预测。从国民经济到社会生活的日益信息化,标志着通信与信息科技的空前发展。

为了满足高等院校师生教改和教学的需求以及广大技术人员学习通信与信息新技术的需要,电子工业出版社约请北京地区的清华大学、北京大学、北京航空航天大学、北京邮电大学、北方交通大学、北京理工大学,南京地区的东南大学、解放军理工大学、南京邮电学院,上海地区的上海交通大学,成都地区的西南交通大学、电子科技大学,西安地区的西安电子科技大学、西安交通大学,天津地区的南开大学,深圳地区的深圳大学,东北地区的哈尔滨工业大学等全国知名高等院校教学第一线上的教授和信息产业部有关科研院所的专家,请他们推荐和反复论证,从国外优秀的英文版图书中精选出版了这套《通信与信息科学教育丛书》(英文版)。

本套丛书可作为高等院校通信、计算机、电子信息等专业的高年级本科生、研究生的教材或教学参考书,也适合广大信息产业技术人员参考。

本套丛书所选取的均是国际上通信与信息科学领域具有代表性的经典著作,它们在全世界许多大学被用做教材或教学参考书。其主要特点是具有较强的先进性、实用性和权威性。丛书内容丰富,深入浅出,层次清楚,理论与应用并重,能够较好地引导读者将现代通信信息与信息科学的原理、技术与应用有机结合。我们希望本套丛书能够进一步推动国内高等院校教学与国际接轨,同时满足广大技术人员及时学习通信与信息科学领域中新知识的需求。

恳请广大读者提出宝贵意见和建议(E-mail: davidzhu@phei. com. cn),以使我们奉献更多、更好的英文原版精品图书。

CONTENTS

PREFACE	ix
1 INTRODUCTION	1
1.1 Motivation	1
1.2 Wireless Signaling Environment	3
1.2.1 Single-User Modulation Techniques	3
1.2.2 Multiple-Access Techniques	5
1.2.3 Wireless Channel	7
1.3 Basic Receiver Signal Processing for Wireless	13
1.3.1 Matched Filter/RAKE Receiver	13
1.3.2 Equalization	17
1.3.3 Multiuser Detection	19
1.4 Outline of the Book	21
2 BLIND MULTIUSER DETECTION	27
2.1 Introduction	27
2.2 Linear Receivers for Synchronous CDMA	28
2.2.1 Synchronous CDMA Signal Model	28
2.2.2 Linear Decorrelating Detector	30
2.2.3 Linear MMSE Detector	31
2.3 Blind Multiuser Detection: Direct Methods	32
2.3.1 LMS Algorithm	34
2.3.2 RLS Algorithm	35
2.3.3 QR-RLS Algorithm	37
2.4 Blind Multiuser Detection: Subspace Methods	41
2.4.1 Linear Decorrelating Detector	41
2.4.2 Linear MMSE Detector	43

2.4.3	Asymptotics of Detector Estimates	45
2.4.4	Asymptotic Multiuser Efficiency under Mismatch	46
2.5	Performance of Blind Multiuser Detectors	49
2.5.1	Performance Measures	49
2.5.2	Asymptotic Output SINR	51
2.6	Subspace Tracking Algorithms	59
2.6.1	PASTd Algorithm	62
2.6.2	QR-Jacobi Methods	66
2.6.3	NAHJ Subspace Tracking	68
2.7	Blind Multiuser Detection in Multipath Channels	71
2.7.1	Multipath Signal Model	71
2.7.2	Linear Multiuser Detectors	73
2.7.3	Blind Channel Estimation	77
2.7.4	Adaptive Receiver Structures	82
2.7.5	Blind Multiuser Detection in Correlated Noise	86
2.8	Appendix	93
2.8.1	Derivations for Section 2.3.3	93
2.8.2	Proofs for Section 2.4.4	95
2.8.3	Proofs for Section 2.5.2	96
3	GROUP-BLIND MULTIUSER DETECTION	109
3.1	Introduction	109
3.2	Linear Group-Blind Multiuser Detection for Synchronous CDMA	110
3.3	Performance of Group-Blind Multiuser Detectors	119
3.3.1	Form II Group-Blind Hybrid Detector	119
3.3.2	Form I Group-Blind Detectors	125
3.4	Nonlinear Group-Blind Multiuser Detection for Synchronous CDMA	129
3.4.1	Slowest-Descent Search	133
3.4.2	Nonlinear Group-Blind Multiuser Detection	135
3.5	Group-Blind Multiuser Detection in Multipath Channels	140
3.5.1	Linear Group-Blind Detectors	143
3.5.2	Adaptive Group-Blind Linear Multiuser Detection	151
3.5.3	Linear Group-Blind Detection in Correlated Noise	155
3.5.4	Nonlinear Group-Blind Detection	158
3.6	Appendix	161
3.6.1	Proofs for Section 3.3.1	161
3.6.2	Proofs for Section 3.3.2	166

4 ROBUST MULTIUSER DETECTION IN NON-GAUSSIAN CHANNELS	173
4.1 Introduction	173
4.2 Multiuser Detection via Robust Regression	175
4.2.1 System Model	175
4.2.2 Least-Squares Regression and Linear Decorrelator	176
4.2.3 Robust Multiuser Detection via M -Regression	177
4.3 Asymptotic Performance of Robust Multiuser Detection	182
4.3.1 Influence Function	182
4.3.2 Asymptotic Probability of Error	183
4.4 Implementation of Robust Multiuser Detectors	187
4.5 Robust Blind Multiuser Detection	197
4.6 Robust Multiuser Detection Based on Local Likelihood Search	201
4.6.1 Exhaustive-Search and Decorrelative Detection	201
4.6.2 Local-Search Detection	204
4.7 Robust Group-Blind Multiuser Detection	206
4.8 Extension to Multipath Channels	211
4.8.1 Robust Blind Multiuser Detection in Multipath Channels	212
4.8.2 Robust Group-Blind Multiuser Detection in Multipath Channels	213
4.9 Robust Multiuser Detection in Stable Noise	215
4.9.1 Symmetric Stable Distribution	216
4.9.2 Performance of Robust Multiuser Detectors in Stable Noise	219
4.10 Appendix	222
4.10.1 Proof of Proposition 4.1 in Section 4.4	222
4.10.2 Proof of Proposition 4.2 in Section 4.5	223
5 SPACE-TIME MULTIUSER DETECTION	225
5.1 Introduction	225
5.2 Adaptive Array Processing in TDMA Systems	226
5.2.1 Signal Model	226
5.2.2 Linear MMSE Combining	228
5.2.3 Subspace-Based Training Algorithm	230
5.2.4 Extension to Dispersive Channels	237
5.3 Optimal Space-Time Multiuser Detection	239
5.3.1 Signal Model	241
5.3.2 Sufficient Statistic	242
5.3.3 Maximum-Likelihood Multiuser Sequence Detector	245

5.4	Linear Space-Time Multiuser Detection	247
5.4.1	Linear Multiuser Detection via Iterative Interference Cancellation	247
5.4.2	Single-User Linear Space-Time Detection	251
5.4.3	Combined Single-User/Multiuser Linear Detection	254
5.5	Adaptive Space-Time Multiuser Detection in Synchronous CDMA	265
5.5.1	One Transmit Antenna, Two Receive Antennas	268
5.5.2	Two Transmit Antennas, One Receive Antenna	273
5.5.3	Two Transmit and Two Receive Antennas	277
5.5.4	Blind Adaptive Implementations	281
5.6	Adaptive Space-Time Multiuser Detection in Multipath CDMA	287
5.6.1	Signal Model	287
5.6.2	Blind MMSE Space-Time Multiuser Detection	294
5.6.3	Blind Adaptive Channel Estimation	295
6	TURBO MULTIUSER DETECTION	303
6.1	Introduction to Turbo Processing	303
6.2	MAP Decoding Algorithm for Convolutional Codes	308
6.3	Turbo Multiuser Detection for Synchronous CDMA	313
6.3.1	Turbo Multiuser Receiver	313
6.3.2	Optimal SISO Multiuser Detector	317
6.3.3	Low-Complexity SISO Multiuser Detector	319
6.4	Turbo Multiuser Detection with Unknown Interferers	328
6.4.1	Signal Model	328
6.4.2	Group-Blind SISO Multiuser Detector	329
6.4.3	Sliding Window Group-Blind Detector for Asynchronous CDMA	335
6.5	Turbo Multiuser Detection in CDMA with Multipath Fading	339
6.5.1	Signal Model and Sufficient Statistics	339
6.5.2	SISO Multiuser Detector in Multipath Fading Channels	342
6.6	Turbo Multiuser Detection in CDMA with Turbo Coding	346
6.6.1	Turbo Code and Soft Decoding Algorithm	346
6.6.2	Turbo Multiuser Receiver in Turbo-Coded CDMA with Multipath Fading	351
6.7	Turbo Multiuser Detection in Space-Time Block-Coded Systems	356
6.7.1	Multiuser STBC System	357
6.7.2	Turbo Multiuser Receiver for STBC System	361
6.7.3	Projection-Based Turbo Multiuser Detection	367

6.8	Turbo Multiuser Detection in Space-Time Trellis-Coded Systems	370
6.8.1	Multiuser STTC System	370
6.8.2	Turbo Multiuser Receiver for STTC System	373
6.9	Appendix	380
6.9.1	Proofs for Section 6.3.3	380
6.9.2	Derivation of the LLR for the RAKE Receiver in Section 6.6.2	381

INTRODUCTION

1.1 Motivation

Wireless communications is one of the most active areas of technology development of our time. This development is being driven primarily by the transformation of what has been largely a medium for supporting voice telephony into a medium for supporting other services, such as the transmission of video, images, text, and data. Thus, similar to the developments in wireline capacity in the 1990s, the demand for new wireless capacity is growing at a very rapid pace. Although there are, of course, still a great many technical problems to be solved in wireline communications, demands for additional wireline capacity can be fulfilled largely with the addition of new private infrastructure, such as additional optical fiber, routers, switches, and so on. On the other hand, the traditional resources that have been used to add capacity to wireless systems are radio bandwidth and transmitter power. Unfortunately, these two resources are among the most severely limited in the deployment of modern wireless networks: radio bandwidth because of the very tight situation with regard to useful radio spectrum, and transmitter power because mobile and other portable services require the use of battery power, which is limited. These two resources are simply not growing or improving at rates that can support anticipated demands for wireless capacity. On the other hand, one resource that is growing at a very rapid rate is that of processing power. Moore's Law, which asserts a doubling of processor capabilities every 18 months, has been quite accurate over the past 20 years, and its accuracy promises to continue for years to come. Given these circumstances, there has been considerable research effort in recent years aimed at developing new wireless capacity through the deployment of greater intelligence in wireless networks (see, e.g., [145, 146, 270, 376, 391] for reviews of some of this work). A key aspect of this movement has been the development of novel signal transmission techniques and advanced receiver signal processing methods that allow for significant increases in wireless capacity without attendant increases in bandwidth or power requirements. The purpose of this book is to present some of the most recent of these receiver signal processing methods in a single place and in a unified framework.

Wireless communications today covers a very wide array of applications. The telecommunications industry is one of the largest industries worldwide, with more than \$1 trillion in annual revenues for services and equipment. (To put this in per-

spective, this number is comparable to the gross domestic product of many of the world's richest countries, including France, Italy, and the United Kingdom.) The largest and most noticeable part of the telecommunications business is telephony. The principal wireless component of telephony is mobile (i.e., cellular) telephony. The worldwide growth rate in cellular telephony is very aggressive, and analysts report that the number of cellular telephony subscriptions worldwide has now surpassed the number of wireline (i.e., fixed) telephony subscriptions. Moreover, at the time of this writing in 2003, the number of cellular telephony subscriptions worldwide is reportedly on the order of 1.2 billion. These numbers make cellular telephony a very important driver of wireless technology development, and in recent years the push to develop new mobile data services, which go collectively under the name *third-generation* (3G) *cellular*, has played a key role in motivating research in new signal processing techniques for wireless. However, cellular telephony is only one of a very wide array of wireless technologies that are being developed very rapidly at the present time. Among other technologies are wireless piconetworking (as exemplified by the Bluetooth radio-on-a-chip) and other personal area network (PAN) systems (e.g., the IEEE 802.15 family of standards), wireless local area network (LAN) systems (exemplified by the IEEE 802.11 and HiperLAN families of standards, called WiFi systems), wireless metropolitan area network (MAN) systems (exemplified by the IEEE 802.16 family of standards, called WiMax systems), other wireless local loop (WLL) systems, and a variety of satellite systems. These additional wireless technologies provide a basis for a very rich array of applications, including local telephony service, broadband Internet access, and distribution of high-rate entertainment content such as high-definition video and high-quality audio to the home, within the home, to automobiles, and so on (see, e.g., [9, 41, 42, 132, 159, 161, 164, 166, 344, 361, 362, 365, 393–395, 429, 437, 449, 457, 508, 558, 559] for further discussion of these and related applications). Like 3G, these technologies have spurred considerable research in signal processing for wireless.

These technologies are supported by a number of transmission and channel-assignment techniques, including time-division multiple access (TDMA), code-division multiple access (CDMA), and other spread-spectrum systems, orthogonal frequency-division multiplexing (OFDM) and other multicarrier systems, and high-rate single-carrier systems. These techniques are chosen primarily to address the physical properties of wireless channels, among the most prominent of which are multipath fading, dispersion, and interference. In addition to these temporal transmission techniques, there are spatial techniques, notably beamforming and space-time coding, that can be applied at the transmitter to exploit the spatial and angular diversity of wireless channels. To obtain maximal benefit from these transmission techniques, to exploit the diversity opportunities of the wireless channel, and to mitigate the impairments of the wireless channel, advanced receiver signal processing techniques are of interest. These include channel equalization to combat dispersion, RAKE combining to exploit resolvable multipath, multiuser detection to mitigate multiple-access interference, suppression methods for co-channel interference, beamforming to exploit spatial diversity, and space-time processing to

jointly exploit temporal and spatial properties of the signaling environment. These techniques are all described in the ensuing chapters.

1.2 Wireless Signaling Environment

1.2.1 Single-User Modulation Techniques

To discuss advanced receiver signal processing methods for wireless, it is useful first to specify a general model for the signal received by a wireless receiver. To do so, we can first think of a single transmitter, transmitting a sequence or *frame* $\{b[0], b[1], \dots, b[M-1]\}$ of channel symbols over a wireless channel. These symbols can be binary (e.g., ± 1), or they may take on more general values from a finite alphabet of complex numbers. In this treatment, we consider only *linear* modulation systems, in which the symbols are transmitted into the channel by being modulated linearly onto a signaling waveform to produce a transmitted signal of this form:

$$x(t) = \sum_{i=0}^{M-1} b[i]w_i(t), \quad (1.1)$$

where $w_i(\cdot)$ is the modulation waveform associated with the i th symbol. In this expression, the waveforms can be quite general. For example, a single-carrier modulation system with carrier frequency ω_c , baseband pulse shape $p(\cdot)$, and symbol rate $1/T$ is obtained by choosing

$$w_i(t) = A p(t - iT) e^{j(\omega_c t + \phi)}, \quad (1.2)$$

where $A > 0$ and $\phi \in (-\pi, \pi)$ denote carrier amplitude and phase offset, respectively. The baseband pulse shape may, for example, be a simple unit-energy rectangular pulse of duration T :

$$p(t) = p_T(t) \triangleq \begin{cases} \frac{1}{\sqrt{T}}, & 0 \leq t < T, \\ 0, & \text{otherwise,} \end{cases} \quad (1.3)$$

or it could be a raised-cosine pulse, a bandlimited pulse, and so on. Similarly, a direct-sequence spread-spectrum system is produced by choosing the waveforms as in (1.2) but with the baseband pulse shape chosen to be a spreading waveform:

$$p(t) = \sum_{j=0}^{N-1} c_j \psi(t - jT_c), \quad (1.4)$$

where N is the spreading gain, $c_0, c_1, \dots, c_{N-1}$, is a pseudorandom spreading code (typically, $c_j \in \{+1, -1\}$), $\psi(\cdot)$ is the chip waveform, and $T_c \triangleq T/N$ is the chip interval. The chip waveform may, for example, be a unit-energy rectangular pulse of duration T_c :

$$\psi(t) = p_{T_c}(t). \quad (1.5)$$

Other choices of the chip waveform can also be made to lower the chip bandwidth. The spreading waveform of (1.4) is periodic when used in (1.2), since the same spreading code is repeated in every symbol interval. Some systems (e.g., CDMA systems for cellular telephony) operate with *long spreading codes*, for which the periodicity is much longer than a single symbol interval. This situation can be modeled by (1.1) by replacing $p(t)$ in (1.2) by a variant of (1.4) in which the spreading code varies from symbol to symbol; that is,

$$p_i(t) = \sum_{j=0}^{N-1} c_j^{(i)} \psi(t - j T_c). \quad (1.6)$$

Spread-spectrum modulation can also take the form of frequency hopping, in which the carrier frequency in (1.2) is changed over time according to a pseudorandom pattern. Typically, the carrier frequency changes at a rate much slower than the symbol rate, a situation known as *slow frequency hopping*; however, *fast hopping*, in which the carrier changes within a symbol interval, is also possible. Single-carrier systems, including both types of spread spectrum, are widely used in cellular standards, in wireless LANs, Bluetooth, and others (see, e.g., [42, 131, 150, 163, 178, 247, 338, 361, 362, 392, 394, 407, 408, 449, 523, 589]).

Multicarrier systems can also be modeled in the framework of (1.1) by choosing the signaling waveforms $\{w_i(\cdot)\}$ to be sinusoidal signals with different frequencies. In particular, (1.2) can be replaced by

$$w_i(t) = A p(t) e^{j(\omega_i t + \phi_i)}, \quad (1.7)$$

where now the frequency and phase depend on the symbol number i but all symbols are transmitted simultaneously in time with baseband pulse shape $p(\cdot)$. We can see that (1.2) is the counterpart of this situation with time and frequency reversed: All symbols are transmitted at the same frequency but at different times. (Of course, in practice, multiple symbols are sent in time sequence over each of the multiple carriers in multicarrier systems.) The individual carriers can also be direct-spread, and the baseband pulse shape used can depend on the symbol number i . (For example, the latter situation is used in *multicarrier CDMA*, in which a spreading code is used across the carrier frequencies.) A particular case of (1.7) is OFDM, in which the baseband pulse shape is a unit pulse p_T , the intercarrier spacing is $1/T$ cycles per second, and the phases are chosen so that the carriers are orthogonal at this spacing. (This is the minimal spacing for which such orthogonality can be maintained.) OFDM is widely believed to be among the most effective techniques for wireless broadband applications and is the basis for the IEEE 802.11a high-speed wireless LAN standard (see, e.g., [354] for a discussion of multicarrier systems).

An emerging type of wireless modulation scheme is ultra-wideband (UWB) modulation, in which data are transmitted with no carrier through the modulation of extremely short pulses. Either the timing or amplitude of these pulses can be used to carry the information symbols. Typical UWB systems involve the transmission of many repetitions of the same symbol, possibly with the use of a direct-sequence
