## Preface

These Lecture Notes were prepared from notes taken by M. Ratliff and K. Spackman of lectures given at the University of Colorado.

I have tried to present a proof as simple as possible of Weil's theorem on curves over finite fields. The notions of "simple" or "elementary" have different interpretations, but I believe that for a reader who is unfamiliar with algebraic geometry, perhaps even with algebraic functions in one variable, the simplest method is the one which originated with Stepanov. Hence it is this method which I follow.

The length of these Notes is perhaps shocking. However, it should be noted that only Chapters I and III deal with Weil's theorem. Furthermore, the style is (I believe) leisurely, and several results are proved in more than one way. I start in Chapter I with the simplest case, i.e., with curves  $y^d = f(x)$ . At first I do the simplest subcase, i.e., the case when the field is the prime field and when  $d$  is coprime to the degree of  $f$ . This special case is now so easy that it could be presented to undergraduates. The general equation  $f(x,y) = 0$  is taken up only in Chapter III, but a reader in a hurry could start there. The second chapter, on character sums and exponential sums, is included at such an early stage because of the many applications in number theory. Chapters IV, V and VI deal with equations in an arbitrary number of variables.

Possible sequences are chapters

I by itself, or

I, III for Weil's theorem, or

I.1, III for a reader who is in a hurry, or

I, II for character sums and exponential sums, or

I, II, IV, or

I, III, IV.3 and V .

Originally I had planned to include Bombieri's version of the Stepanov method. I did include it in my lectures at the University of Colorado, but I first had to prove the Riemann-Roch Theorem and basic properties of the zeta function of a curve. A proof of these basic properties in the Lecture Notes would have made these unduly long, while their omission would have made the Bombieri version not self complete. Hence I decided after some hesitation to exclude this version from the Notes.

Recently Deligne proved far reaching generalizations of Weil's theorem to non-singular equations in several variables, thereby confirming conjectures of Weil. It is to be noted, however, that Deligne's proof rests on an assertion of Grothendieck concerning a certain fixed point theorem. To the best of my knowledge, a proof of this fixed point theorem has not appeared in print yet. It is perhaps needless to say that at present there is no elementary approach to such a generalization of Weil's theorem. But it is to be hoped that some day such an approach will become available, at least for those cases which are used most often in analytic number theory.

November, 1975

W. M. Schmidt

# Notation

$F^*$  is the multiplicative group of a field  $F$ .  
 $\bar{F}$  is the algebraic closure of a field  $F$ .  
 $F^n$  is the product  $F \times \dots \times F$ , i.e., the set of  $n$ -tuples  $(x_1, \dots, x_n)$  with  $x_i \in F$  ( $i = 1, \dots, n$ ).  
 $[F_1 : F_2]$  denotes the degree of a field extension  $F_1 \supset F_2$ .  
 $\text{Tr}$  denotes the trace and  $\eta$  the norm.  
 $F_q$  will denote the finite field with  $q$  elements.  
 $p$  will be the characteristic.  
 $\mathbb{Q}$  is the field of rational numbers,  
 $\mathbb{R}$  the field of reals,  
 $\mathbb{C}$  the field of complex numbers,  
 $\mathbb{Z}$  the ring of (rational) integers.  
 $\cong$  denotes isomorphism of fields or groups.

Quite often,  $x, y, z, \dots$  will be elements which lie in a ground field or are algebraic over a ground field,  $X, Y, Z, \dots$  will be variables, i.e., will be algebraically independent over a ground field, and  $\xi, \eta, \dots$  will be algebraic functions, i.e., they will be algebraically dependent on some of  $X, Y, \dots$ . Thus  $f(X_1, \dots, X_n)$  is a polynomial, and  $f(x_1, \dots, x_n)$  is the value of this polynomial at  $(x_1, \dots, x_n)$ .

$F(x)$  or  $F(X)$  or  $F(X, Y)$  or  $F(X, \eta)$ , or similar, will be the field obtained by adjoining  $x$  or  $X$  or  $X, Y$  or  $X, \eta$  to a ground field  $F$ . Thus  $F(X)$  is the field of rational functions in a variable  $X$  with coefficients in  $F$ .  $R[X]$  denotes the ring of polynomials in  $X$  with coefficients in the ring  $R$ .

If  $a, b$  are in  $Z$ , we write  $a|b$  (or  $a \div b$ ) if  $a$  does (or does not) divide  $b$ . Occasionally we shall write  $d|q-1$  instead of the more proper notation  $d|(q-1)$ . Again, we shall write  $f(X)|g(X)$  if the polynomial  $f(X)$  divides  $g(X)$ . Further  $(f(X))$  (or  $(f(X), g(X))$ ) will be the ideal generated by  $f(X)$  (or by  $f(X)$  and  $g(X)$ ).

$|w|$  denotes the number of elements of a finite set  $w$ . Given sets  $A \subseteq B$ , the set theoretic difference is denoted by  $B \sim A$ .

## Introduction

Gauss (1801) made an extensive study of quadratic congruences modulo a prime  $p$ . He also obtained the number of solutions of the cubic congruence

$$ax^3 - by^3 \equiv 1 \pmod{p}$$

for primes  $p = 3n+1$ , and of the quartic congruence

$$ax^4 - by^4 \equiv 1 \pmod{p}$$

for primes  $p = 4n+1$ . He studied the congruence

$$ax^4 - by^2 \equiv 1 \pmod{p}$$

for arbitrary primes  $p$ .

Artin (1924) considered the congruence  $y^2 \equiv f(x) \pmod{p}$ ,

where  $f(X)$  is a polynomial whose leading coefficient is not divisible by  $p$  and which has no multiple factors modulo  $p$ , and made the following conjecture: The number  $N$  of solutions satisfies

$$|N - p| \leq 2\sqrt{p} \quad \text{if } \deg f = 3,$$

$$|N+1 - p| \leq 2\sqrt{p} \quad \text{if } \deg f = 4.$$

This conjecture was proved by Hasse (1936 b,c.). In fact, let  $F_q$  be the finite field with  $q$  elements, and let  $N$  be the number of solutions  $(x,y) \in F_q^2$  of the equation  $y^2 = f(x)$ , where  $f(X)$  is a polynomial with coefficients in  $F_q$  and with distinct roots. Then

$$|N - q| \leq 2\sqrt{q} \quad \text{if } \deg f = 3,$$

$$|N+1 - q| \leq 2\sqrt{q} \quad \text{if } \deg f = 4.$$

Suppose  $f(X,Y)$  is a polynomial of total degree  $d$ , with coefficients in  $F_q$  and with  $N$  zeros  $(x,y)$  with coordinates in  $F_q$ . Suppose  $f(X,Y)$  is absolutely irreducible, i.e., irreducible not only over  $F_q$ , but also over every algebraic extension thereof.

Weil (1940, 1948a)<sup>†</sup> proved the famous theorem (the "Riemann Hypothesis for Curves over Finite Fields") that

$$(1) \quad |N - q| \leq 2g\sqrt{q} + c_1(d)$$

where  $g$  is the "genus" of the curve  $f(x, y) = 0$  and where  $c_1(d)$  is a constant depending on  $d$ . It can be shown that  $g \leq \frac{1}{2}(d-1)(d-2)$ , hence that

$$|N - q| \leq (d-1)(d-2)\sqrt{q} + c_1(d).$$

Weil's proof depends on algebraic geometry, in particular on Castelnuovo's inequality. A somewhat simpler proof was given by Roquette (1953); see also Lang (1961), Eichler (1963).

More recently, Stepanov (1969, 1970, 1971, 1972a, 1972b, 1974) gave a new proof of special cases of Weil's result which does not depend on algebraic geometry, but which is related to Thue's (1908) method in diophantine approximation. This method consists in the construction of a polynomial in one variable with rather many zeros. The construction is by the method of undetermined coefficients.

In particular, Stepanov proved that

$$(2) \quad |N - q| \leq c_2(d)\sqrt{q}$$

if  $f(X, Y)$  is of some special type, for instance if

$$f(X, Y) = Y^d - f(X)$$

where  $d$  and the degree of  $f$  are coprime. Later Bombieri (1973)

and Schmidt proved (2) for absolutely irreducible  $f(X, Y)$  by the

Thue - Stepanov method. It follows from the theory of the zeta function that (2) implies (1).

In these Lectures we shall prove (2) by the Stepanov method.

---

<sup>†</sup>The 1940 paper is only an announcement.

# I. Equations $y^d = f(x)$ and $y^q - y = f(x)$ .

## § 1. Finite Fields (Galois fields).

Let  $F$  be any field. There is a smallest subfield  $k \subseteq F$  (the intersection of all subfields of  $F$ ), called the prime subfield of  $F$ , and either  $k = \mathbb{Q}$  or  $k = F_p$ , the integers modulo a prime  $p$ . In the first case  $F$  is of characteristic 0, in the second case of characteristic  $p$ . In the case when  $F$  is finite,  $k = F_p$ , and  $[F : F_p]$  is finite. If, say,  $[F : F_p] = \kappa$ , then  $|F| = p^\kappa$ . Hence if  $F_q$  is a field with  $q$  elements, then  $q = p^\kappa$ ,  $p$  prime.

Let  $F_q$  be a finite field and let  $F_q^*$  be the multiplicative group of  $F_q$ . Then  $|F_q^*| = q - 1$ . If  $x \in F_q^*$ , then  $x^{q-1} = 1$ ; hence, for  $x \in F_q$ , we have  $x^q - x = 0$ . Therefore,  $X^q - X = \prod_{x \in F_q} (X - x)$ . So  $F_q$  is the splitting field of  $X^q - X$  over  $F_p$ , and  $F_q$  is a normal extension of  $F_p$ . Moreover, as a splitting field,  $F_q$  is unique up to isomorphisms.

Conversely, let  $F$  be the splitting field of  $X^q - X$  over  $F_p$ , where  $q = p^\kappa$ . Let  $x_1, \dots, x_q$  be the roots of this polynomial in  $F$ . These roots are distinct since the derivative  $D(X^q - X) = -1 \neq 0$ . Now  $x_i + x_j$  is a root of  $X^q - X$ , since,

$$(x_i + x_j)^q - (x_i + x_j) = x_i^q + x_j^q - x_i - x_j = 0,$$

and similarly for  $x_i - x_j$ . Also  $x_i x_j$  is a root, since

$$(x_i x_j)^q = x_i^q x_j^q = x_i x_j,$$

and similarly  $x_i/x_j$  is a root if  $x_j \neq 0$ . These roots clearly form a field, so, in fact,  $F = \{x_1, x_2, \dots, x_q\}$ . Thus a field with  $q$  elements does exist.

Considering the above, we have:

THEOREM 1A. If  $F_q$  is a finite field of order  $q$ , then  
 $q = p^k$ ,  $p$  prime. For every such  $q$ , there exists exactly  
one field  $F_q$ . This field is the splitting field of  $X^q - X$   
over  $F_p$ , and all of its elements are roots of  $X^q - X$ .

THEOREM 1B. The multiplicative group  $F_q^*$  is cyclic.

For the proof of this theorem we need

LEMMA 1C. Let  $G$  be a finite group of order  $d$ . Suppose  
for every divisor  $e$  of  $d$ , there are at most  $e$  elements  
 $x \in G$  with  $x^e = 1$ . Then  $G$  is cyclic.

The theorem follows immediately, since  $X^e - 1$  has at most  $e$  roots in  $F_q^*$ . It only remains to give a

Proof of Lemma 1C. Every element of  $G$  is of some order  $e$ , where  $e|d$ . Let  $\psi(e)$  be the number of elements of  $G$  whose order is  $e$ . Either  $\psi(e) = 0$  or  $\psi(e) \neq 0$ . Suppose  $\psi(e) \neq 0$ , and let  $y \in G$  have order  $e$ . Then the elements  $y, y^2, \dots, y^e = 1$  are distinct and all satisfy  $x^e = 1$ . Since there are  $e$  of these elements, by hypothesis there can be no other elements  $x \in G$  satisfying  $x^e = 1$ .

Now let  $z \in G$  be any element of order  $e$ ; then  $z = y^i$  ( $1 \leq i \leq e$ ). Notice that  $z = y^i$  has order  $e$  precisely if  $(i, e) = 1$ . Hence  $\psi(e) = \varphi(e)$ , where  $\varphi$  is the Euler  $\varphi$ -function. So, in general,  $\psi(e) \leq \varphi(e)$ , taking into account the possibility that  $\psi(e) = 0$ . But

$$d = \sum_{e|d} \psi(e) \leq \sum_{e|d} \varphi(e) = d.$$

Hence, for every divisor  $e$  of  $d$ ,  $\psi(e) = \varphi(e)$ ; in particular,  $\psi(d) = \varphi(d) \neq 0$ . That is, there exists an element of order  $d$ ; hence,  $G$  is cyclic.

COROLLARY 1D. Let  $q = p^k$ . Then  $F_q = F_p(x)$  for some  $x$ .

Proof. Let  $x$  be a generator of  $F_q^*$ .

Let  $F_q \subseteq F_r$  be finite fields; then  $r = q^h$ . Consider the mapping  $\omega: F_r \rightarrow F_r$  such that  $\omega(x) = x^q$ . This mapping is one-one.

For suppose  $x^q = y^q$ , then

$$0 = x^q - y^q = (x - y)^q,$$

whence  $x - y = 0$  and  $x = y$ . The mapping  $\omega$  is then one-one

of a finite set to itself, hence is onto. Moreover,  $\omega$  is an automorphism of  $F_r$ , since

$$\omega(x + y) = (x + y)^q = x^q + y^q = \omega(x) + \omega(y)$$

$$\text{and } \omega(xy) = (xy)^q = x^q y^q = \omega(x) \omega(y).$$

In fact,  $\omega$  is an automorphism of " $F_r$  over  $F_q$ " (leaving  $F_q$  fixed), since if  $x \in F_q$ ,  $\omega(x) = x^q = x$ . In other words,

$\omega$  is a member of the Galois group of  $F_r$  over  $F_q$ . The map  $\omega$  is called the "Frobenius automorphism".

If  $r = q^K$ , then  $1, \omega, \omega^2, \dots, \omega^{K-1}$  are automorphisms of  $F_r$  over  $F_q$ , and they are distinct because if

$$\omega^i = \omega^j \quad (0 \leq i, j \leq K-1),$$

then  $\omega^i(x) = \omega^j(x)$  for all  $x \in F_r$ ,

$$x^{q^i} = x^{q^j} \quad \text{for all } x \in F_r,$$

so  $x^{q^i} - x^{q^j} = 0$  for all  $x \in F_r$ .

But the degree of the polynomial  $x^{q^i} - x^{q^j}$  is less than  $q^K = r$ , so the above cannot hold identically for all  $x \in F_r$ , unless  $x^{q^i} - x^{q^j}$  is identically zero and  $i = j$ . Since the order of the Galois group is  $K$ , these are the only automorphisms of  $F_r$  over  $F_q$ . We have shown:

THEOREM 1E. Every automorphism of  $F_r$  over  $F_q$  is of the form  $\omega^i$  ( $0 \leq i \leq K-1$ ), where  $\omega(x) = x^q$ . That is, the Galois group of  $F_r$  over  $F_q$  is cyclic with generator  $\omega$ .

Recall that the trace of an element is the sum of its conjugates. For the case  $F_q \subseteq F_r$ , the trace of an element  $x \in F_r$  is

$$\text{Tr}(x) = x + x^q + x^{q^2} + \dots + x^{q^{K-1}}.$$
