PREFACE

This book is designed to focus on research progress of endodontics and periodontology in recent years and to guide the students to understand the trends of those fields, establishing their scientific attitude to explore the unknown knowledge. The part for Endodontics is divided into 6 chapters, determination of root canal working length, development and application on micro root canal treatment, root canal retreatment, strategies to the problems in the process of root canal treatment, the effect of oval canal on root canal treatment, radiographic aids in root canal treatment. The part of periodontology is divided into 5 chapters, frontiers in periodontal microbiology, research progress of aetiology from systemic disorders, periodontal initial therapy, the progress of periodontal regenerative therapy, and the periodontal medicine outline.

CONTENTS

PREFACE

CHAPTER I DETERMINATION OF ROOT CANAL WORKING LENGTH 001

PART I GENERAL DESCRIPTION 001

1.1 Significance of Working Length in Root Canal Treatment 001

1.2 Theoretical Basis of Precise Determination 002

PART II COMMON METHODS FOR WORKING LENGTH DETERMINATION 002

2.1 History of Working Length Determination 002

2.2 Concept, Operation And Significance of Tactile Method 003

2.2 Concept, Operation And Significance of Radiographic Method 004

2.3 Concept, Operation And Significance of Electronic Method 004

PART III DETERMINATION OF THE ROOT CANAL WORKING LENGTH 006

3.1 Anatomic Foundation of the Apical Area 006

3.2 Clinical Methods in Precise Determination of Working Length 007

3.3 Clinical Technique with Electronic Apex Locators 008

3.4 Clinical Consideration on Working Length Determination 008

3.4 Operation Announcements 011

REFERENCES 011

CHAPTER II DEVELOPMENT AND APPLICATION ON MICRO ROOT CANAL TREATMENT 012

PART I DEVELOPMENT OF SURGICAL MICROSCOPE 012

PART II CHARACTERISTIC OF SURGICAL MICROSCOPE 013

2.1 Magnification 013

2.2 Illumination 013

PART III ADVANTAGE COMBINED WITH RCT AND SURGICAL MICROSCOPE 013

Search Root Canal Orifice 013

PART IV MANAGING CANAL CALCIFICATION AND BLOCKAGE 014

PART V MANAGING INSTRUMENTS SEPARATION 015

PART VI MICRO-ULTRASONIC TECHNOLOGY 015

PART VII MICRO-TUBE TECHNIQUE 015

PART VIII	PERFORATION REPAIR	017
PART IX	CRACK DETECTION	018
PART X	PERIAPICAL SURGERY	018
	Instruments Comparison	018
PART XI	COMPARISON BETWEEN TRADITIONAL AND MICROSURGERY	018

CHAPTER III ROOT CANAL RETREATMENT 022

PART I	CAUSES FOR FAILURE OF ENDODONTIC TREATMENT	022
PART II	INDICATION OF RETREATMENT	023
	2.1 Indication of Retreatment	023
	2.2 Contraindication of Retreatment	023
	2.3 The Risk And Advantage of Retreatment	024
PART III	PROCEDURES FOR RETREATMENT	024
	3.1 Removal of Crown	024
	3.2 Management of Root Canal Omittance	024
	3.3 Removal of Gutta-percha	025
	3.4 Management of Calcification	025
	3.5 Management of Ledge	026
	3.6 Management of Root Perforation	027
PART IV	POST-TREATMENT CONSIDERATIONS	028
	4.1 Flare-up	028
	4.2 Final Coronal Restoration	028
	4.3 Follow-up Visits	028
	4.4 Prognosis for Healing	028
	REFERENCES	028

CHAPTER IV STRATEGIES TO THE PROBLEMS IN THE PROCESS OF ROOT CANAL TREATMENT 030

PART I	LOSS OF WORKING LENGTH	030
PART II	ROOT CANAL BLOCKAGE	030
PART III	LEDGE FORMATION	031
PART IV	TRANSPORTATION	033
	4.1 Canal Transportation	033
	4.2 Zip Formation	033
	4.3 Elbow Formation	033
PART V	PERFORATIONS	034
	5.1 Four Dimeusious of A Perforation	034
	5.2 Cervical Canal Perforations	035

5.3 Midroot Perforations 035

5.4 Apical Perforations 035

PART VI INADEQUATE OR INAPPROPRIATE ENLARGING AND SHAPING THAT HINDER THE PROVISION OF QUALITY TREATMENT 035

6.1 Enlarging And Shaping Beyond the Canal Terminus 035

6.2 Excessive Removal of Root Dentin 036

6.3 Failure to Properly Enlarge And Shape the Canal 036

CHAPTER V THE EFFECT OF OVAL CANAL ON ROOT CANAL TREATMENT..... 037

PART I THE DEFINITION AND PREVALENCE OF OVAL CANAL 037

1.1 The Definiton of Oval Canal 037

1.2 Occurrence of Oval Canal 037

PART II PREPARATION OF OVAL CANAL 039

2.1 Mechanical Preparation 039

2.2 Machine Preparation Methods 039

2.3 Chemical Prepare 040

PART III OBTURATION OF OVAL ROOT CANALS 040

3.1 Cold Lateral Condensation of Gutta-percha 041

3.2 Warm Gutta-percha Fillings 041

3.3 Conclusion 042

REFERENCES 042

CHAPTER VI RADIOGRAPHIC AIDS IN ROOT CANAL TREATMENT 044

PART I INTRAORAL PERIAPICAL RADIOGRAPHY 044

1.1 Principles of Periapical Radiography 044

1.2 Limitations of the Periapical Radiography 044

1.3 Interpretation of Radiograph 045

PART II COMPUTED TOMOGRAPHY (CT) 045

2.1 The Traditional CT 045

2.2 Cone-beam CT 045

2.3 Application of Cone Beam CT in Endodontics 046

REFERENCES 047

CHAPTER VII FRONTIERS IN PERIODONTAL MICROBIOLOGY 050

PART I CURRENT CONCEPT AND PROGRESS FOR SUBGINGIVAL BIOFILM RESEARCH 050

1.1 Formation And Construction of Subgingival Biofilm 050

1.2 Bacterial Community of Subgingival Biofilm 052

1.3 Multiple Interspecies Interactions And Special Bacterial Behavior in Subgingival

PART II	CURRENT CONCEPT IN PATHOGENICITY OF PERIODONTAL PATHOGENS	058
2.1	Current Concept of Periodontal Pathogens	058
2.2	Progress of Periodontal Primary Pathogenic Bacteria Research	058
2.3	Progress of Periodontal Virus Research	062
PART III	OVERVIEW OF MICROBIAL ETIOLOGY IN PERIODONTAL DISEASE	064
	REFERENCES	065

CHAPTER VIII RESEARCH PROGRESS OF AETIOLOGY FROM SYSTEMIC DISORDERS 066

PART I	STRESS AND PSYCHOLOGICAL FACTORS	066
1.1	What Is Stress?	066
1.2	Stress Influence Life-style	067
1.3	Interaction Between Stress And Periodontal Disease	068
PART II	RHEUMATOID ARTHRITIS AND PERIODONTAL DISEASE	068
2.1	RA May Be A Causal Factor for Periodontitis	069
2.2	Periodontitis May Be A Causal Factor for RA	070
2.3	Genetic Factors in RA And Periodontitis	070
PART III	OBESITY AND PERIODONTAL DISEASE	070
3.1	Definition And Classification of Obesity	070
3.2	Prevalence of Obesity	070
3.3	Obesity-Related Diseases	071
3.4	Relationship Between Obesity And Periodontal Disease, Animals Experiments	071
3.5	Relationship Between Obesity And Periodontal Disease, Epidemiological Studies	071
3.6	Biological Mechanisms	072
PART IV	CIGARETTE SMOKING AND PERIODONTAL DISEASE	073
4.1	Smoking, A Risk Factor for Periodontitis	073
4.2	Mechanisms of Periodontal Disease Progression in Smokers	073
4.3	Effects of Smoking on Periodontal Therapy	075

PART I GENERAL DESCRIPTION

Root canal treatment (RCT) is the process of infected root canal being shaped, cleaned and obturated. The objectives of shaping and cleaning are to remove pulp tissue, debris, and bacteria, as well as to prepare the canal for obturation. This step plays a key role in successful root canal treatment.

Determination of working length is the first step of preparation. Working length is designated for the distance preparation instruments inserted into the canal attain. Meanwhile, the width and taper of prepared canal are also important factors for successful RCT.

1.1 Significance of Working Length in Root Canal Treatment

Correct working length determination comprises one of the most critical steps in endodontic treatment. Determination of working length is the first step of root canal preparation. When working length is determined longer than it should be, the exces-

sive movement of instruments beyond the apical constriction (AC) will push the bacteria in the root canal into the periapical area, or directly violate the periodontal ligament and alveolar bone. On the other hand, loss of the apical constriction leads to/ cause an open apex with an increased likelihood of overfilling, lack of an adequate apical seal, and pain and discomfort for the patient. When working length is determined too short, the root canal will not be prepared deep enough, so that bacteria in the apical portion may survive and multiply. Besides, when working length is not correctly determined, the taper and width of instruments will not fit for the root canal. As a result, somewhere of the canal wall is not prepared enough while somewhere of the canal wall may be overprepared. In consequence, the success rate of RCT drops. The apical 3 mm of the root canal system has been considered to be a critical zone in the treatment of infected canal.

In conclusion, determination of the working length is the main factor leading to success in RCT. Correct working length determination is essential for perfect root canal preparation, and then makes it

cleaning and filling easier.

1.2 Theoretical Basis of Precise Determination

In the process of tooth development, dentin is formed by odontoblast in pulp tissue, and then cementogenesis is initiated by cementoblast after root dentin formation. There is a distinct borderline between the two hard tissues, namely Cementum-dentin junction (CDJ). It is the point where pulp tissue ends and periodontal tissues begin. Therefore, preparation in RCT should stop at CDJ.

Theoretically, CDJ is considered as an ideal termination for RCT. CDJ is a junction of dentin, cementum and periodontium. Periapical blood circulation can reach this point. One third of the apical surface cementum is regenerative, and induced odontoblast from periodontium or residual vital pulp can regenerate dentin tissue. Therefore, a successful RCT is expected to create an environment conducive to the regeneration of cementum even dentin, which will seal the AF so that the root canal can be free from infection. However, CDJ is a histological mark and it is not a fixed point. Its location in the root canal is highly variable. So it is impossible to determine CDJ in clinic.

Clinically, the final working length would be reached by considering both radiographic measurements and the accuracy of electronic apex locators, together with the knowledge of the anatomy of the root apex. It is impossible to get the exact position of CDJ with the three methods alone or together. This is only an estimate.

Therefore, how to decrease the error to the greatest extent with these methods makes sense in working length determination.

PART II COMMON METHODS FOR WORKING LENGTH DETERMINATION

2.1 History of Working Length Determination

Methods for working length determination were developed along with the improvement in knowledge of teeth anatomy, root canal treatment approaches as well as science techniques. Initially, working length was determined by tactile method and paper point method. Then radiography is being used in working length determination. The exact measurement was achieved by using hand instruments and the subsequent translation with the assistance of gauges. Radiography is a traditional method of obtaining information on the anatomy of the root canal and its surrounding tissue, which is still widely used in working length determination. In 1942, Suzuki found that there was a constant resistance of

6.5k Ω at a defined current between the periodontal membrane and oral mucosa in dogs, which did not vary with ages, sex, teeth position and situation of patients. In 1962, Sunada developed the first apex locator, working with direct current based on this assumption. The first-generation (resistance) locators detected the point where the file displaces from within the canal to the periodontal ligament, whereas the second-generation devices were based on the impedance principle. The reliability of these systems was approximately 55% to 75%, although their main inconvenience was the fact that the presence of pus, pulp remains, or irrigating solutions within the canal led to erroneous readings. To improve the measurement procedure, direct current was replaced by alternating current, and the frequencies used were varied and sometimes isolated. In addition, bipolar and oscillating electrodes were used. Integrated resistance adjustment was dropped, as it proved to be untenable. In 1984, a difference method was introduced by Yamashita as a new principle of measurement. This method used two different frequencies for the first time with two matching resistances and impedances. The apical constriction was determined from the difference between the two. Kobayashi and Suda improved this idea of relative impedance measurement and introduced the 'ratio method' in 1991, creating an impedance quotient instead of a difference.

All the types of apex locators are designed on the basis of the constant resistance between the periodontal membrane and oral mucosa. They are different from each other in the types of the outer impressed current. So far, there are five generations of electronic apex locators:

First- and second-generation models (resistance-type) work with direct current by measuring the resistance. This model is susceptible to many interference factors and has been eliminated.

Third-generation (impedance-type) works with two different frequencies current by measuring impedance. This model is assisted by computer process and can provide a relative precise data (Fig. 1-1).

Fig. 1-1 Third-generation (impedance-type) apex locator.

Fourth-generation (impedance-type) works with multiple frequency alternating current by measuring resistance and impedance separately. This type is impressed by more than two frequencies and the resistance and impedance under defined current were detected separately, which can improve the precision (Fig. 1-2).

Fifth-generation (frequency-type) is the newest model which works with variable frequency current by calculating the impedance ratio under different voltage ratios. This method is free from the interference factors in root canal to the maximum extent. Therefore, frequency-type locators can operate in a canal filled with pus and tissue (Fig. 1-3).

2.2 Concept, Operation And Significance of Tactile Method

Tactile method works by feeling the AC with intra-canal instruments. Stop advancing the instrument when there is a resistance, and this point is considered the working length termination (Fig. 1-4).

Tactile method requires that the clinician to have a good knowledge of the tooth anatomy and adequate experience. Therefore, the success rate of this method varies among clinicians. There is a study which demonstrating that the success rate of RCT for a professional clinician using tactile method alone in working length determination was about 60%. In cases with periapical diseases, the suc-

Fig. 1-2 Fourth-generation (impedance-type) apex locator.

Fig. 1-3 Fifth-generation (frequency-type) apex locator.

Fig. 1-4 Tactile method for working length determination.

cess rate drops. Because when there is a periapical lesion, both the apex cementum and the periapical alveolar bone can be resorbed, so that the position of AC is altered or even disappears. In cases with intra-canal calculus, the canal was blocked and hard to get through. Obviously, tactile method is not enough for clinical practice and it is scarcely performed alone to determine working length in clinic recently. However, tactile method still plays an important role in dredging the root canal with instruments. The ideal use of tactile method would be to minimize the number of radiographic exposures by

making an accurate estimate of the working length before any radiographic measurement. For example, tactile method can be used to insert the file to a relative correct position before taking a radiograph. If the file is not located correctly in advance, we will not get the useful information from the radiograph. Besides, the exited file may destroy the periapical tissue and cause discomfort. The manual technique obviously depends on the sensitivity of the operator. Therefore, as a dentist, it is essential to master the apical anatomy and the mean working length of every tooth (Table 1-1).

Table 1-1 Means of the Teeth Length for Chinese People

	Teeth Length (mm)	Corona Root Ratio	Teeth Length (Wang) (mm)
Maxillary			
Central incisor	22.5	1:1.25	22.5
Lateral incisor	22	1:1.47	21.5
Canine	26.5	1:1.71	25.2
First premolar	20.6	1:1.51	20.5
Second premolar	21.5	1:1.86	20.5
First molar	20.8	1:1.71	19.7
Second molar	20.2	1:1.80	19.3
Mandibular			
Central incisor	20.5	1:1.34	19.9
Lateral incisor	21	1:1.32	21
Canine	25.5	1:1.48	24.6
First premolar	21.6	1:1.79	20.9
Second premolar	22.3	1:1.83	20.5
First molar	21	1:1.72	20.5
Second molar	19.8	1:1.86	19.1

Cited from Means of the teeth length for Chinese people, Huiyuun Wang.

2.2 Concept, Operation And Significance of Radiographic Method

Calculation of the working length by radiographic method is made with respect to the position of the radiographic apex. Radiography is the traditional method of obtaining information on the anatomy of the root canal and its surrounding tissue.

However, the radiographic method is unreliable in determining the position of the AC or AF. When the radiographic apex does not coincide with AC or even with the AF, the measurement will be incorrect. Besides, radiography is sensitive both in its exposure and interpretation. It depends on a series of factors: tooth inclination, film position, length of the beam cone, vertical and horizontal

cone angulation, and so forth. Moreover, the main inconvenience is that this approach is entirely subjective and therefore scanty reproducible. Data shows that 82% AF are found to be located by the radiographic method alone. However, AF of 50% maxillary canines, 25% maxillary molars and 23% maxillary central incisors are hardly located by radiographic method alone.

AF can be located at any position of the apex, labial/buccal side, lingual/palatal side, mesial side or distal side (Fig. 1-5 to Fig. 1-9).

2.3 Concept, Operation And Significance of Electronic Method

Electronic method is an approach to measure root canal working length by detecting the position of periodontal ligament with electronic devices. Different generations of electronic apex locators were
