Preface

The number of electric motors in the 1- to 125-hp range was approximately 70 million in 1977 and is increasing 6 percent per year according to a recent study by the U.S. Department of Energy. This study also noted that 53 to 58 percent of the electric energy generated is consumed by electric-motor-driven systems. This presents us with an opportunity to save considerable energy by wisely selecting motors and the devices they drive. However, it should be recognized that the electric motor is a device for converting electrical energy to rotating mechanical energy. The only power consumed by the electric motor is the electrical and mechanical energy losses within the motor, and the balance of the electrical energy is transferred as mechanical energy to some driven device such as a pump, fan, or conveyor. Since the motor losses are 5 to 25 percent of the input power, it is important to consider the complete system, including the electric motor, when determining system efficiency and potential energy conservation.

Modern motors are precisely designed, taking advantage of computer-derived optimum designs, high-quality materials, and improved manufacturing technology. Hence, for many years the trend was toward smaller and lighter motors in order to lower cost, and no significant attention was given to efficiency and the power factor beyond the levels required to achieve allowable temperatures.

With the increasing cost of electric power, in 1975 motor manufacturers began addressing the problem of improving electric motor efficiencies to levels that would represent significant savings in energy.

Coincident with the trend toward smaller motors, many users

and original equipment manufacturers have been choosing to purchase the lowest-first-cost motor without considering the power factor and efficiency. Similarly, many textbooks and handbooks on electric motors discuss in great detail the design and performance characteristics of electric motors and the characteristics of various types of motor loads and how to match the motor to the load requirements. However, efficiency, the power factor, energy costs, and life-cycle costing have not been considered as major factors in the selection of an electric motor in most applications.

In many cases, electric motors have been selected and applied by engineers or other personnel who have a limited knowledge of electric motors, particularly a lack of understanding of the power factor, efficiency, and associated energy economies.

Today, with the high cost of electrical energy and the continuing trend toward higher costs, electric motors should be applied and selected on a life-cycle cost basis, including such factors as first cost, energy efficiency, the duty cycle, operating time, and energy costs.

My goal in this book is to provide guidelines for selecting and applying electric motors on an energy conservation and life-cycle cost basis. Particular emphasis is given to both single-phase and three-phase motors in the 1- to 125-hp range since this is the range that offers the maximum opportunities for energy savings. It is my intention to present these guidelines in a format that can be understood and effectively used by all personnel responsible for the application, selection, and procurement of electric motors, motor controls, and motor-driven products.

John C. Andreas

Induction Motor Characteristics

1.1 THREE-PHASE INDUCTION MOTORS

In the integral horsepower sizes, i.e., above 1 hp, three-phase induction motors of various types drive more industrial equipment than any other means. The most common three-phase (polyphase) induction motors fall within the following major types:

NEMA* design B: Normal torques, normal slip, normal locked amps

NEMA design A: High torques, low slip, high locked amps

NEMA design C: High torques, normal slip, normal locked amps

NEMA design D: High locked-rotor torque, high slip

Wound rotor: Characteristics depend on external resistance

Multispeed: Characteristics depend on design—variable torque, constant torque, constant horsepower

There are many specially designed electric motors with unique characteristics to meet specific needs. However, the majority of needs can be met with the preceding motors.

NEMA Design B Motors

The NEMA design B motor is the basic integral horsepower motor. It is a three-phase motor designed with normal torque and normal starting current and generally has a slip at the rated load of less than 4 percent. Thus the motor speed in revolutions per minute is 96 percent or more

*National Electrical Manufacturers Association.

of the synchronous speed for the motor. For example, a four-pole motor operating on a 60-Hz line frequency has a synchronous speed of 1800 rpm or a full-load speed of

$$\begin{aligned} 1800 - (1800 \times \text{slip}) &= 1800 - (1800 \times 0.4) \\ &= 1800 - 72 \\ &= 1728 \text{ rpm} \end{aligned}$$

or

$$1800 \times 0.96 = 1728 \text{ rpm}$$

In general, most three-phase motors in the 1- to 125-hp range have a slip at the rated load of approximately 3 percent, or in the case of four-pole motors, a full-load speed of 1745 rpm. Figure 1.1 shows the typical construction for a totally enclosed, fan-cooled NEMA design B motor with a die-cast aluminum single-cage rotor.

Figure 1.2 shows the typical speed-torque curve for the NEMA design B motor. This type of motor has moderate starting torque, a

Fig. 1.1 NEMA design B totally enclosed, fan-cooled polyphase induction motor. (Courtesy of Gould Inc., Electric Motor Division, St. Louis.)

Fig. 1.2 NEMA design B motor speed-torque curve.

pull-up torque exceeding the full-load torque, and a breakdown torque (or maximum torque) several times the full-load torque. Thus it can provide starting and smooth acceleration for most loads and in addition can sustain temporary peak loads without stalling. The NEMA performance standards for design B motors are shown in Table 1.1, Table 1.2, and Table 1.3. There are no established standards for the efficiency or the power factor of NEMA design B motors. However, NEMA has established standards for testing and labeling motors; these standards are discussed in detail in Chap. 2.
