# Preface

In the symbiotic associations of plant and fungi, arbuscular mycorrhiza, which is formed between plants and Glomeromycota fungi, has the widest distribution in the nature. Arbuscular mycorrhizal (AM) fungi inhabit a variety of ecosystems including agricultural lands, forests, grasslands and various stressful environments, and colonize the roots of most plants, including bryophyte, pteridophyte, gymnosperm and angiosperm, etc.. They are recognized as an important, widespread component of most terrestrial ecosystems, benefiting plant establishment by enhancing plant nutrient acquisition, improving soil quality, and increasing resistance to environmental stresses, and also playing significant roles in maintaining plant biodiversity, ecosystem variability and productivity, and in remediating environmental problems.

According to the latest taxonomy, AM fungi belong to the Glomeromycota phylum, including 14 families and 26 genera. To date, although only fewer than 200 species of AM fungi have been described, numerous studies on AM fungal diversity in different ecosystems worldwide have shown that AM fungi distribute globally. A total of 134 AM fungi species within 13 genera, including 12 new species, have been reported in various environments in China since the earliest studies in 1980's. Although considerable research efforts have been carried out on AM fungal biodiversity, these studies are unsystematic and not enough. China has a large area of land and diverse ecosystems with various environmental factors, thus AM fungal resources and diversity may be abundant and need study systematically.

The book provided the authors' latest research results. The first four chapters summarily reviewed AM fungal biodiversity in China, and then typically studied AM fungal biodiversity in forest ecosystems, desert ecosystems, and the saline-alkali soil. The latter six chapters focused on the application of AM fungi in improving plant nutrition, accelerating the environmental remediation of polluted sites, and improving the quality and safety of agricultural products.

Dr. Fayuan Wang wrote approximately 146 000 words in Chapter 1, Chapter 4, and Chapters 6-10, and Dr. Zhaoyong Shi wrote another 140 000 words in Chapters 2-3, and Chapter 5.

We have referred much previously published papers in the whole manuscript (especially in the first Chapter). The references are provided in the final section of the book, but we wish to give special thanks to all the authors and publishers. The studies involved in this book were financed by the National Natural Science Foundation (Grant Nos. 40801120 and 40971150) and the China Postdoctoral Science Foundation. We also thank the Scholarly Monograph Publication Funds of Henan University of Science and Technology, for providing financial support towards publication of the manuscript.

# Chapter 1 Biodiversity of Arbuscular Mycorrhizal Fungi in China

## 1.1 Introduction

Arbuscular mycorrhizal (AM) fungi are extremely common symbioses in terrestrial ecosystems, associating with about 80% of plant families worldwide. They are recognized as an important, widespread component of most terrestrial ecosystems, benefiting plant establishment by enhancing plant nutrient acquisition, improving soil quality, and increasing resistance to environmental stresses (Smith and Read, 1997), and also playing an important role in plant biodiversity, ecosystem variability and productivity. According to the latest taxonomy, AM fungi belong to the Glomeromycota phylum, including 14 families and 26 genera. To date, although only fewer than 200 species of AM fungi have been described (Redecker and Philipp, 2006), numerous studies on AM fungal diversity in different ecosystems worldwide have shown that AM fungi distribute globally (Treseder and Cross, 2006).

China is situated in the eastern part of Asia, with a coastline of 18 000 km and a total land area of 9.6 million km<sup>2</sup>. Its territory extends over 50° of latitude from north to south, embracing the equatorial belt, the tropics, the subtropics, the moderate temperate zone, and the cold temperate zone. From east to west, China extends over 62° of longitude with land covered by forests, grasslands, deserts, plains, hills, and mountains. China has a marked continental monsoonal climate characterized by great variety. Northerly winds prevail in winter, while southerly winds reign in summer. China has 94.97 million ha of cultivated land, 400 million ha of grasslands, and 133.7 million ha of forests. The diversity of plant species in China is extraordinary, about 30 000 or one-eighth of the world total.

Studies on AM fungal biodiversity in China began in the 1980's. In 1984, Tang

and Zang reported the first new AM fungus *Glomus citricolum* (Tang and Zang, 1984). Thereafter, more and more survey work and classification of AM fungi within China were carried out. Over the past 20 years, more than 100 papers on AM fungal biodiversity have been published. This review aims to summarize the advances in AM fungal biodiversity, including species diversity, habitat diversity and host diversity within China.

## 1.2 Materials and Methods

The data were obtained by collecting the published reports about arbuscular mycorrhizal fungi in China.

## 1.3 Results

### 1.3.1 AM fungal species diversity

A total of 134 AM fungi species within 13 genera have been reported in the rhizosphere of different plants in various environments in China, including 12 new species (Table 1-1). The most common and widely distributed genus is *Glomus* (69 species), and then *Acaulospora* (28 species) and *Scutellospora* (17 species).

Notes: The scientific names are amended according to the internet information (<http://www.lrz-muenchen.de/~schuessler/amphylo/>).

\* New species from China.

### 1.3.2 AM fungal habitat diversity

It has been shown that, besides farmlands (Gai et al., 2004; Peng et al., 1990; Zhang and Wang, 1991), fruit lands (Jiang et al., 2007; Liu et al., 1987), vegetable lands (Wang et al., 2006), forest lands (Fang et al., 2006; Hu, 1988), grasslands (Bao et al., 2007; Cai et al., 2005; Wang et al., 2003; Xue et al., 2007), AM fungi occurred widely in tropical rain forests (Shi et al., 2003; Shi et al., 2003; Zhao et al., 2001; Zhao et al., 2001), tropical virgin forests (Gong et al., 1994), tropical secondary forest (Fang et al., 2006), artificial forests (Gong et al., 1996; Yi et al., 1990), natural secondary forests (Chen and Zhuang, 1997), greenhouse vegetable land (Liu et al., 2001), natural reserves (Ren et al., 2005; Wu et al., 2000), altiplano grassland, etc. (Cai et al., 2005).

AM fungi occurred in all kinds of landforms all over the China, such as mountains (Shi et al., 2007; Zhang and Wang, 1991), plateaus (Cai et al., 2005; Pan et al., 1997;

Pan et al., 1997), hills (Gai and Liu, 2000), plains (Gai and Liu, 2000), islands (Liu et al., 2001), basin (Wang et al., 2006). However, AM fungal biodiversities differ from different soil climatic zones, varying with various environmental factors (Zhang et al., 1998; Zhang et al., 1999).

In recent years, AM fungal diversities in fragile ecosystems and polluted environments received more attraction, such as deserts (Bao et al., 2005; Ji et al., 2007; Tian et al., 2006), saline-alkaline soils (Sheng et al., 2007; Tang et al., 2007; Wang and Liu, 2002; Zhang et al., 2007), degraded grasslands (Wang et al., 2003), eroded soils (Pan et al., 1997; Pan et al., 1997), sewage irrigated soils (Geng et al., 2002), petroleum polluted soils (Huang et al., 2007), coal mine heaps (Wang et al., 2003), heavy metal polluted soils (Liang et al., 2007), mining disturbed soils (Zhang et al., 2006), mine tailings (Chen et al., 2005), abandoned mine lands (Liang et al., 2007).

### 1.3.3 AM fungal host diversity

AM fungi are ubiquitous in natural ecosystems, associating with about 80% of terrestrial plant species worldwide (Smith and Read, 1997). Most plant phyla, including bryophyte, pteridophyte, gymnosperm and angiosperm, are all able to form mycorrhizae with AM fungi. In China, crops, wild plants, tropical plants, alpine plants, halophytes, xerophyte, hydrophyte, geophyte, parasitic plants, are all found to be mycorrhizal. Only a few families, such as Cyperaceae, Brassicaceae, Caryophyllaceae, Juncaceae, Chenopodiaceae and Amaranthaceae, are assumed never to form mycorrhizal associations or to do so rarely (Hirsch and Kapulnik, 1998). In recent years, mycorrhizae on plants of these families have been observed, such as Cyperaceae (Muthukumar et al., 2003), Amaranthaceae (Bao and Yan, 2004; Chen et al., 2001; Yang et al., 2002), Caryophyllaceae (Chen et al., 2001), and Chenopodiaceae (Liu et al., 2002; Wang and Liu, 2002).

China has about 30,000 plant species, accounting for about one eighth of the world total. Chinese researchers have done a considerable amount of work on the mycorrhizal status of plant species in terrestrial ecosystems and have examined a total of nearly 800 plant species belonging to 150 families. These plants include food crops, economic crops, vegetables, fruits, ornamental plants, Chinese medical plants, wild weeds, trees, etc. (Table 1-2). Interestingly, even some forest trees, such as *Eucalyptus* and Dipterocarpaceae, usually considered to be typically ectomycorrhizal, have been recently

found to have AM colonization (Gong et al., 1996; Shi et al., 2003; Shi et al., 2003).

Table 1-2 Plant species reported to be AM in China

| Plants         | Plant species                                    |                                            | References                                                                                                                                                        |
