Preface

With chromatography as many substances as possible should be separated from each other as well as possible. A poor separation is not “repairable” later. However, we have the impression that the following evaluation and assessment of the results are not always treated with due caution under everyday stress. One likes to rely on the computer programs – finally the integration software is validated and this is “covered” by the manufacturer’s certificate. It is hardly registered as a problem that the integration algorithms have changed only insignificantly for 30 years and that the area of peaks merged together is always determined simply by perpendicular drop. The assessment of the results is often based on consideration of the questions: “Does the c.v. match?” and “Is my value in spec?” Sometimes this may suffice, sometimes not.

We would like to deal with the following questions in this book: How accurate are the integrated areas or heights of commercial systems? Can one check this at all? How important are the integration parameters, what effect do they have on results? However, we also wanted to have a look at the questions: “How can I really judge a result?” How correct can a result be in reality?” and finally: “What do the authorities have to say on this subject, what must I do, what am I free to do?” To this end we have invited experienced colleagues who have made their knowledge available in various areas. Our many thanks are due to these colleagues.

On the one hand, it is the aim of the book to show that one perhaps should not always blindly trust integration systems and that it is worthwhile developing a deeper appreciation of integrating. On the other hand, we want to make a contribution to the critical analysis of chromatographic results, primarily for quantitative statements used as a basis for decisions. We hope to give the reader many suggestions and ideas for finding his own “right” evaluation and assessment practice. We thank the WILEY-VCH publishing house, and particularly Lesley Belfit and Frank Weinreich, for very close cooperation.

Structure of the Book

Part 1: Evaluation and Estimation of Chromatographic Data

In Part 1 it is shown, how chromatographic data are obtained and how the results are evaluated.

In Chapter 1 (Hans-Joachim Kuss and Daniel Stauffer) it is described how a chromatogram arises and which factors influence the shape, the height and the area of the peaks. The most important equations for Gaussian or exponential modified Gaussian (EMG) peaks are given.

In Chapter 2 (Daniel Stauffer and Hans-Joachim Kuss) the integration parameters are explained: What do they mean and what are they called in different integration systems.

Chapter 3 (Hans-Joachim Kuss) deals mainly with the integration and integration errors. The question considered is the accuracy of commercial integration systems. Furthermore, the possibility of checking this using a chromatogram simulation is described with Gaussian peaks to verify the results.

Chapter 4 (Uwe Neue) treats the simulation of EMG-peaks and gives the theoretical background for peaks in gradient hplc.

Chapter 5 (Hans-Joachim Kuss) describes the special difficulties of the integration of asymmetric (EMG)-peaks.

Chapter 6 (Mike Hillebrand) treats the possibility of “recalculating” merged peaks with the deconvolution method.

Chapter 7 (Hans-Joachim Kuss) treats the calculations for evaluation and calibration, including weighted calibration.

The general criteria for the judgement of analytical data are introduced systematically and analyzed critically in Chapter 8 (Joachim Ermer).

Most of the chromatograms and/or tables in Chapters 3 to 8 can be found on the supplementary CD. The examples are ordered following the book’s table of contents. Each time a remark such as “Chromatogram.cdf” or “Table.xls” is found in the text, the corresponding file can be found on the CD.

Part 1 concludes with Chapter 9 (Ulrich Panne) which considers the metrological aspects of analytical data together with a detailed discussion of the measuring uncertainty.

Part 2: Characterization of the Evaluation of Different Chromatographic Modes

The evaluation of chromatographic results depends on the chromatographic techniques used. An overview is given of some special conditions for: Gas chromatography in Chapter 10 (Werner Engewald), LCMS coupling in Chapter 11 (Hartmut Kirchherr), ion chromatography in Chapter 12 (Heiko Herrmann and Detlef Jensen) and gel permeation chromatography in Chapter 13 (Daniela Held and Peter Kilz).

Part 3: Requirements for Chromatographic Data Analysis from the Viewpoint of Organisations and Public Authorities

The area regulated most strongly is certainly the pharmaceutical one. The requirements are explained from three different viewpoints: the US guidelines in Chapter 14 (Linda Ng), the EU guidelines in Chapter 15 (Ulrich Rose) and the view of the pharmaceutical industry in Chapter 16 (Joachim Ermer). Instead of an epilogue, the everyday dealing with analysis results is discussed in the final Chapter 17 (Stavros Kromidas).

The individual chapters were written to represent closed modules, but “jumping” between them is possible at any time. It is the aim of the editors to introduce a book of ideas and to give a lot of suggestions so that one can possibly find one’s own solutions. Therefore, the divergent opinions of the authors on topics were accepted. Some repetitions were also accepted so as not to impair the harmony in the textual context. The reader may profit from the different representation of the topics and the individual weighting of the authors.
