CHAPTER 1

- Fig. 1.1. The vicinity of Factory Point, Vermont, later called Manchester, as shown in the *Atlas of Bennington County, Vermont*, published in 1869. 6
- Fig. 1.2. Topography in the vicinity of Manchester, Vermont, as shown on a portion of the Equinox, Vermont U.S. Geological Survey 15-minute quadrangle map, 1894. 7
- Fig. 1.3. Land use and land cover in the vicinity of Manchester, Vermont, as shown on a portion of the Glens Falls, New York, U.S. Geological Survey Land Use and Land Cover Map, 1972. 8
- Fig. 1.4. Increased rate of technological improvement as illustrated by generalized relationship between year of inception of a technology and Lienhard's time-constant of change. 12

CHAPTER 2

- Fig. 2.1. Elements of route planning in navigation. 16
- Fig. 2.2. Street grid is aligned to river bank in The Dalles, Oregon, and to nearby northeast-southwest trending ridges in State College, Pennsylvania. 18
- Fig. 2.3. Scale diagram of a rebelib, or group chart, of the Ralik chain in the Marshall Islands. 19
- Fig. 2.4. Atoll struck by a set of generally parallel primary wave crests, which are both refracted and reflected, produces an interference pattern of primary and secondary wave crests, which serve as navigation cues for boatmen in the Marshall Islands. 20

- Fig. 2.5. Portion of a portolan chart prepared in 1529 by Diego Ribero, Spain's Royal Cosmographer. 22
- Fig. 2.6. With increased distance from the equator, the distortion of angles on a square grid increases as increased east-west stretching distorts circles into ellipses. 23
- Fig. 2.7. On the equatorially centered Mercator projection, parallels are spaced progressively farther apart with increased distance from the equator so that a straight line between points A and B represents a line of constant bearing called a rhumb line. 24
- Fig. 2.8. A great circle route, plotted as a simple straight line on a gnomonic projection, can be approximated by a series of rhumb lines on a Mercator projection. 25
- Fig. 2.9. Latitude is the angle above the equator of the specified parallel, and longitude is the angle between the prime meridian and the specified meridian. 27
- Fig. 2.10. The zenith angle, between the Sun's rays at noon and a straight line from the center of the Earth, is equal to latitude. 28
- Fig. 2.11. As the Earth rotates from west to east at 15 degrees per hour, the Sun moves from east to west. 29
- Fig. 2.12. Stationary air horn emits a concentric pattern of sound waves, which are received as a series of evenly spaced wave crests. 32
- Fig. 2.13. Decreased spacing of waves from horn of single locomotive approaching off-track position can be used to estimate two possible locations of observing station. 33
- Fig. 2.14. Sonar measures water depth from bottom of ship by determining time required for sound waves to return to sensor after reflection from sea floor. 35
- Fig. 2.15. Hyperbola through X, Y, and Z is locus of all points at which time difference is $3a + u$ for pulses broadcast from M and rebroadcast $5a + u$ time units later from S. 36
- Fig. 2.16. Set of master and slave stations produces a pattern of hyperbolic lines of position, each representing a unique time difference. 37
- Fig. 2.17. Radar altimeter of a cruise missile scans ahead to measure distance to ground and generate grid of rela-

tive elevation values to compare with stored digital terrain maps. 39

Fig. 2.18. Generalized profile of Tomahawk cruise missile after descending to low altitude as it approaches coast. 41

Fig. 2.19. Cruise missile's Digital Scene Matching Area Correlator (DSMAC) detects designated target by matching sensed ground features with digital representation carried onboard. 42

CHAPTER 3

Fig. 3.1. Gunner's quadrant was inserted in the bore of a cannon so that the angle of elevation could be read against the plumb line. 49

Fig. 3.2. Plane table is used to draw accurate angles between lines of sight, so that distant points can be plotted by intersection. 50

Fig. 3.3. Graduated vertical rod and libella illustrate principles of leveling, the measurement of both horizontal and vertical distances between points. 51

Fig. 3.4. Upper and lower stadia hairs etched into the objective lens of a transit telescope are separated by vertical distance h . 53

Fig. 3.5. Generalized electronic distance measurement system. 55

Fig. 3.6. Adjusted trilateration networks with exaggerated error ellipses representing a 95-percent confidence level. 58

Fig. 3.7. Example of the arrangement of horizontal control stations as a chain of quadrilaterals in an arc of a geodetic triangulation network. 59

Fig. 3.8. Generalized maps of geodetic control networks in Pennsylvania, 1980. 60

Fig. 3.9. Ellipsoid is formed by the revolution about the Earth's axis of an ellipse. The geoid is much closer in cross section to an ellipse than to a sphere. 62

Fig. 3.10. Overlapping aerial photographs can be used to measure angles for triangulation and to fix additional control points by intersection. 64

Fig. 3.11. Radial directions from principal point to three con-

trol points are plotted on an overlay to be used in locating the ground nadir by resection on a map showing the correct locations of the control points. 65

Fig. 3.12. Geometry of a single vertical aerial photograph showing radial displacement, focal length, and flight height. 66

Fig. 3.13. Geometry of a pair of overlapping aerial photographs showing the parallax difference between the top and bottom of a flag pole. 67

Fig. 3.14. Simple geometric figures for pit and peak illustrate that, when positioned for stereoviewing, parallax is greater for lower elevations and smaller for higher elevations. 68

Fig. 3.15. Contours are lines of constant elevation that represent the form of a land surface. 69

Fig. 3.16. Orthophotograph can be produced by copying the cells of a fine grid on an aerial photograph so that each grid cell is repositioned to compensate for radial displacement due to relief. 70

Fig. 3.17. Inertial positioning systems are based upon two simple physical systems: the accelerometer and the gyroscope. 73

CHAPTER 4

Fig. 4.1. Portion of a plat map showing section numbers for Public Land Survey townships. 78

Fig. 4.2. Example of detail on a nineteenth-century county atlas. 79

Fig. 4.3. A surveyor's perambulator, or wheelbarrow odometer, for measuring distance. 80

Fig. 4.4. State "cooperation," in unadjusted dollars, and area surveyed: Pennsylvania, 1900–1932. 81

Fig. 4.5. Cumulative area surveyed for large-scale base maps: Pennsylvania and the United States, 1883–1950. 82

Fig. 4.6. Expansion of topographic coverage of Pennsylvania, 1890–1930. 82

Fig. 4.7. Status of topographic map coverage for Pennsylvania, 1946. 83

- Fig. 4.8. Shift from 1:62,500-scale, 15-minute quadrangle sheets to 1:24,000-scale, 7.5-minute quadrangle sheets, 1939–1961. 84
- Fig. 4.9. Pattern of publication dates for 7.5-minute topographic series, 1980. 85
- Fig. 4.10. Spectral “signatures” of healthy green vegetation and green-painted camouflage are similar in the visible part of the spectrum, but clearly distinct in the near-infrared. 90
- Fig. 4.11. The spectral shift of color IR imagery detects objects with a dominant reflectance in the green, red, or near-infrared band but represents these objects symbolically as blue, green, or red, respectively. 91
- Fig. 4.12. Sensitivity of the human eye, conventional color film, color IR film, and Landsat RBV and MSS imagery. 92
- Fig. 4.13. Landsat multispectral scanner system sweeps six scan lines simultaneously in a scan path 185 km [115 mi] long. 93
- Fig. 4.14. Radar pulses reflected from building are stronger and arrive back at the sensor sooner than pulses returning from more distant, less reflective clump of trees. 94
- Fig. 4.15. Scan lines sensed by side-looking airborne radar (SLAR) have a time-pulse strength curve that can be converted to a digital raster image with pixels similar to those of a Landsat scene. 96
- Fig. 4.16. Landsat orbits the Earth 14 times a day in a near-polar orbit, with each orbit crossing the equator about 25 degrees west of the previous crossing. 98
- Fig. 4.17. Features larger than the IFOV but contrasting only mildly with their surroundings may be distinguishable if they dominate a pixel (A), or unrecognizable if diluted by neighboring features when divided among several pixels (B). 99
- Fig. 4.18. Rectangular regions defined by minimum and maximum ground truth reflectances represent land-cover types in a simple, two-channel parallelepiped classifier. 101
- Fig. 4.19. Resampling of original, offset grid of rectangular pixels to a new, geometrically corrected grid of square pixels may

assign the reflectance of an original cell to more than one new cell. 103

Fig. 4.20. Local operators exaggerate pixel's difference from its neighbors in edge enhancement and diminish this difference in smoothing enhancement. 104

Fig. 4.21. Different choropleth maps result for Pennsylvania county population densities expressed as ratio of population to all land and ratio of population to inhabitable urban land only. 107

Fig. 4.22. Computer-produced dot map. 108

CHAPTER 5

Fig. 5.1. State-unit choropleth map of population change illustrates the generalization of boundaries and coastlines common to small-scale thematic maps. 112

Fig. 5.2. Area cartogram deliberately distorts the map areas of data units to make bigger symbols for more important places and smaller symbols for less important places. 113

Fig. 5.3. Block faces combine to form blocks, which, in turn, combine to form census tracts of approximately 4,000 residents. 116

Fig. 5.4. Contents of a DIME record for a street segment permit an address to be matched with its block and tract. 117

Fig. 5.5. Outline map of Maine showing county boundaries as represented in the DIMECO file. 119

Fig. 5.6. Example of a choropleth map produced on a line printer. 121

Fig. 5.7. Example of a contour map produced on a line printer. 123

Fig. 5.8. Principles of X and Y displacement produced by moving gantry of flatbed plotter and rotating drum of a drum plotter. 124

Fig. 5.9. Example of a map produced on a pen plotter. 125

Fig. 5.10. Run-length encoding reduces from 14 to 7 the number of words of memory required to describe this sample scan line. 126

- Fig. 5.11. Schematic representation of a cathode ray tube. 127
- Fig. 5.12. Schematic representation of liquid crystal light valve display. 129
- Fig. 5.13. Example of information loss resulting from removal of hidden lines to enhance three-dimensional effect of oblique view of statistical surface. 131

CHAPTER 6

- Fig. 6.1. Early lithographic printing press with stone plate. 147
- Fig. 6.2. Generalized model of an offset lithographic printing press. 149
- Fig. 6.3. A printing plate coated with a thin photosensitive emulsion is placed in contact with the emulsion side of a photographic negative and exposed to light. 150
- Fig. 6.4. A map engraved in wax by the Matthews-Northrup Works, Buffalo, New York. 152
- Fig. 6.5. Schematic profile of a vacuum frame showing open-window, peelcoat negative, dot screen, and new emulsion, which yields a 20-percent right-reading graytone for an area defined by a wrong-reading open-window in the peelcoat negative. 154
- Fig. 6.6. Schematic production flow diagram for a simple two-color map showing color separations for yellow and cyan and feature separations for woodland, lakes, and streams. 157
- Fig. 6.7. Examples of maps plotted with a photohead on a Gerber Scientific flatbed plotter. 164
- Fig. 6.8. Example of a map plotted with the Scitex Response-250 laser-beam drum plotter. 166
- Fig. 6.9. Schematic diagram of a drum scanner and the scanned raster image. 166
- Fig. 6.10. Example of a map plotted by a Versatec electrostatic dot-matrix printer/plotter. 169
- Fig. 6.11. Schematic diagram of an ink-jet printer. 170
- Fig. 6.12. Schematic map of the ARPANET showing links between nodes. 176

Preface

This book was conceived to explain to students why my introductory course in cartography pays little attention to drafting maps with pen and ink. Many undergraduate students have heard that people skilled in drawing maps have found jobs even in tight recessions, and they become worried when laboratory exercises focus on critiquing design and using computers rather than inking lines and lettering labels. For these readers the book should offer insight on the extent to which computers and other electronic technology will alter the form of the map, increase map use, and reduce the skill and training required to obtain a decent-looking, convincing cartographic display. Because of what I call the Electronic Transition in Cartography, the ability merely to plot a “good looking” map will become as commonplace as the ability to type a “good looking” letter. The good student ought not be discouraged by a lack of drawing ability, and the forward-looking student must plan for change and appreciate the role in mapping of public policy and management as well as design. Cartography, after all, is no more drafting than journalism is typing or chemistry is cooking.

In these essays I explore the changes that electronic technology has made, is making, and probably will make in all principal phases of mapping and map use: navigation, surveying, land information systems, decision support systems, and map publishing. I examine previous technological transitions to assess the extent to which significant inventions can radically transform the content, appearance, use, and worth of maps. Cartography’s Electronic Transition will render the map as much the outcome of a political process as it traditionally has been the product of explo-

ration and craftsmanship. The cartographer, the geographer, the social scientist interested in regional patterns, and the earth scientist must be aware of the complex linkages among the many producers, distributors, and users of geographic information. This book is intended to provide much of the general technical background needed to appreciate the range of problems that mapping policy ultimately must confront.

The book should also interest educators and humanists. It predicts that the digital map will replace the paper map as the principal medium of cartographic storage and analysis, and it forecasts an era in which the immediate user rather than a distant map author/publisher will compose most cartographic displays. Yet it also recognizes that modern telecommunications could foster an increased appreciation and use of maps by journalists and geographers, and thus expand the market for cogent, well-planned presentational cartography. But whether an increased exploitation of the map will serve knowledge and understanding more than hype and glitter is uncertain, for without a graphically literate and geographically astute public, maps may become little more than pleasurable icons employed to seduce and entertain rather than to inform and enlighten.

At a time of increased concern for human survival, parts of this book might anger some readers, as they did one reader of the manuscript who was alienated by my frequent and sometimes enthusiastic mention of military contributions to cartographic innovation. But whatever our politics and social conscience, we cannot deny the strong historical bond between map and soldier, nor can we dispute that much of the present digital cartographic effort is inspired or sustained by a concern for national defense. I cannot convincingly explain and condemn the cruise missile in the same breath, and I choose not to weave into these chapters the uncertain and highly pessimistic threads of my personal doubts about the ability of the world's governments to resist the temptations and threats of nuclear war.

I owe several people a debt of gratitude. Guthrie Birkhead, Dean of the Maxwell School of Citizenship and Public Affairs at Syracuse University, granted me a semester leave to plan and organize this book. Many colleagues graciously read and pro-

vided helpful comments on early drafts of individual chapters: Gregory Bass, Lee Bender, John Bossler, Vinton Cerf, Richard Dahlberg, Andrew Douglas, John Jensen, Jon Leverenz, Robert McMaster, Judy Olson, Timothy Petersen, George Schnell, Anthony Williams, and David Woodward. Michael Kirchoff, Maureen Devey, Andrew Bratton, Michelle Kermes, Ann Perry, Marcia Harrington, Sean Cassidy, David Flinn, and Janet Saxon at the Syracuse University Cartographic Laboratory prepared the artwork for most of the illustrations. Michael Peterson, Joel Morrison, Jon Kimerling, and Barbara Petchenik provided useful suggestions on the complete manuscript. David Woodward was a source of much appreciated encouragement and counsel. My wife Margaret gave me the tolerance and nourishment that makes writing both possible and purposeful.

Contents

Illustrations	ix
Preface	xvii
CHAPTER 1 Introduction	3
A Century of Cartographic Change	5
Mapping and the Rate of Technological Progress	11
Adapting and Institutions	13
CHAPTER 2 Location and Navigation	15
Map Use Tasks in Navigation	15
Orientation, Wave Crests, and Stick Charts	17
Pilot Charts, Map Grids, and Mercator's Projection	21
Latitude and Longitude, Angles and Time	26
Satellites, the Doppler Shift, and Instant Location	30
Sonar and Loran, Navigation and Mapping	34
Cruise Missiles: Digital Maps and the Unmanned Bomber	38
Map Use, Human Factors, and Optimal Displays	43
"Trickle Down"	44
CHAPTER 3 Boundaries and Surveys	46
Angles and Distances	47
Lasers and Distance Measurement	52
Control Networks: Our Locational Infrastructure	59
Aerotriangulation and Stereoplotting	63
Inertial Positioning: Motion Indicates Distance	71
Geodesy as a Public Utility	74

CHAPTER 4 Aerial Reconnaissance and Land Cover Inventories	76
Topographic Mapping: A Base for Further Detail	77
Aerial Surveying and Photo Interpretation	85
Remote Sensing and Orbiting Platforms	89
Image Analysis and Image Enhancement	100
Policy and Politics	108
CHAPTER 5 Decision Support Systems	110
Maps and Censuses	111
DIME Files and Data Structures	116
Displays, Pointers, and Interactive Maps	126
National Atlases and Data Banks	133
Turnkey Systems and Mapping Software	137
Standards, Cooperation, and Shared Benefits	142
CHAPTER 6 Map Publishing and the Digital Map	144
Printing, Photography, and the Spread of the Map	145
Plastic Film, Scribing, and Feature Separations	153
Computer Memories for the Digital Map	158
Graphic Hardware for the Map Publisher	163
Glass Threads, Networks, and Videotex	171
Maps as Software	178
CHAPTER 7 Summary and Conclusions	181
Summary of the Chapters	182
Problems for Public Policy	184
Security and Digital Data	188
Preservation and the Historical Record	191
Humanistic Challenges	193
Notes	199
Bibliography	229
Glossary	249
Index	273

TECHNOLOGICAL TRANSITION IN CARTOGRAPHY
