## Preface

Does today's man look the same as say, 2 million years ago? Did you know that Pug and Great Dane have the same ancestor? Why children take on some physical and behavioral traits from their parents? All these questions and many more are answered by evolutionary biology (EB). A subfield of biology, EB studies the evolutionary processes that produced the diversity of life on earth as well as the descent and origin of species.

To understand the purpose of EB, we must know a bit of its history. Ancient Romans, Greeks, Chinese, and medieval Islamic science believed that species alter over a period of time. However, the theory was first formally proposed by Jean-Baptiste Lamarck in early 19th century. Further ahead, theories of natural selection and evolution were propagated by Charles Darwin. Though the acceptance of the theory was slow with some exceptions like Germany, etc.; eventually, evolution was agreed upon. That paved way for modern evolutionary synthesis, which involves evidence from various branches of biology like systematics, cytology, morphology, paleontology, etc.

Eventually, EB has reached its current status in the world of science and evolution studies. And the credit goes to evolutionary biologists who have worked hard and made the concept and different theories of evolution comprehensible. Evolutionary biologists like Theodosius Dobzhansky, R. A. Fisher, J. B. S. Haldane, George Gaylord Simpson are very few to name who have immensely contributed to this field. Moreover, it's heartening to see an expanding literature specifically dedicated to the subject.

	Preface	IX
Chapter 1	<b>Physiological and Biochemical Responses of <i>Ulva prolifera</i> and <i>Ulva linza</i> to Cadmium Stress</b> He-ping Jiang, Bing-bing Gao, Wen-hui Li, Ming Zhu, Chun-fang Zheng, Qing-song Zheng and Chang-hai Wang	1
Chapter 2	<b>Genomics Approaches for Crop Improvement against Abiotic Stress</b> Bala Anı Akpınar, Stuart J. Lucas and Hikmet Budak	12
Chapter 3	<b>Some Problems in Proving the Existence of the Universal Common Ancestor of Life on Earth</b> Takahiro Yonezawa and Masami Hasegawa	21
Chapter 4	<b>Complex Tasks Force Hand Laterality and Technological Behaviour in Naturalistically Housed Chimpanzees: Inferences in Hominin Evolution</b> M. Mosquera, N. Geribàs, A. Bargalló, M. Llorente and D. Riba	26
Chapter 5	<b>Drought Tolerance in Modern and Wild Wheat</b> Hikmet Budak, Melda Kantar and Kuaybe Yucebilgili Kurtoglu	38
Chapter 6	<b>Genetic Variation and Population Structure in Jamunapari Goats Using Microsatellites, Mitochondrial DNA, and Milk Protein Genes</b> P. K. Rout, K. Thangraj, A. Mandal and R. Roy	54
Chapter 7	<b>Genetic Diversity and Variability in Endangered Pantesco and Two Other Sicilian Donkey Breeds Assessed by Microsatellite Markers</b> Salvatore Bordonaro, Anna Maria Guastella, Andrea Criscione, Antonio Zuccaro and Donata Marletta	61
Chapter 8	<b>Evolutionary Relationship between Two Firefly Species, <i>Curtos costipennis</i> and <i>C. okinawanus</i> (Coleoptera, Lampyridae), in the Ryukyu Islands of Japan Revealed by the Mitochondrial and Nuclear DNA Sequences</b> Masahiko Muraji, Norio Arakaki and Shigeo Tanizaki	67
Chapter 9	<b>The Low Temperature Induced Physiological Responses of <i>Avena nuda</i> L., a Cold-Tolerant Plant Species</b> Wenying Liu, Kenming Yu, Tengfei He, Feifei Li, Dongxu Zhang and Jianxia Liu	76

Chapter 10	<b>GmNAC5, a NAC Transcription Factor, Is a Transient Response Regulator Induced by Abiotic Stress in Soybean</b> Hangxia Jin, Guangli Xu, Qingchang Meng, Fang Huang and Deyue Yu	83
Chapter 11	<b>Developmental Principles: Fact or Fiction</b> A. J. Durston	88
Chapter 12	<b>Differential Evolutionary Constraints in the Evolution of Chemoreceptors: A Murine and Human Case Study</b> Ricardo D'Oliveira Albanus, Rodrigo Juliani Siqueira Dalmolin, José Luiz Rybarczyk-Filho, Mauro Antônio Alves Castro and José Cláudio Fonseca Moreira	93
Chapter 13	<b>Origins and Evolution of WUSCHEL-Related Homeobox Protein Family in Plant Kingdom</b> Gaibin Lian, Zhiwen Ding, Qin Wang, Dabing Zhang and Jie Xu	102
Chapter 14	<b>Effects of Zoledronic Acid on Physiologic Bone Remodeling of Condylar Part of TMJ: A Radiologic and Histomorphometric Examination in Rabbits</b> Ufuk Tatli, Yakup Üstün, Mehmet Kürkçü and Mehmet Emre Benlidayı	114
Chapter 15	<b>Extensive Introgression among Ancestral mtDNA Lineages: Phylogenetic Relationships of the Utaka within the Lake Malawi Cichlid Flock</b> Dieter Anseeuw, Bruno Nevado, Paul Busselen, Jos Snoeks and Erik Verheyen	120
Chapter 16	<b>Microsatellites Cross-Species Amplification across Some African Cichlids</b> Etienne Bezault, Xavier Rognon, Karim Gharbi, Jean-Francois Baroiller and Bernard Chevassus	129
Chapter 17	<b>Vehicles, Replicators, and Intercellular Movement of Genetic Information: Evolutionary Dissection of a Bacterial Cell</b> Matti Jalasvuori	136
Chapter 18	<b>Divergence in Defence against Herbivores between Males and Females of Dioecious Plant Species</b> Germán Avila-Sakar and Cora Anne Romanow	153
Chapter 19	<b>Deep Phylogenetic Divergence and Lack of Taxonomic Concordance in Species of <i>Astronotus</i> (Cichlidae)</b> Olavo Pinhatti Colatreli, Natasha Verdasca Meliciano, Daniel Toffoli, Izeni Pires Farias and Tomas Hrbek	169
Chapter 20	<b>Genomic Structure and Evolution of Multigene Families: "Flowers" on the Human Genome</b> Hie Lim Kim, Mineyo Iwase, Takeshi Igawa, Tasuku Nishioka, Satoko Kaneko, Yukako Katsura, Naoyuki Takahata and Yoko Satta	177

Chapter 21	<b><i>Drosophila melanogaster</i> Selection for Survival of <i>Bacillus cereus</i> Infection: Life History Trait Indirect Responses</b>	188

Responses of *Ulva prolifera* and *Ulva linza* to Cd<sup>2+</sup> stress were studied. We found that the relative growth rate (RGR), Fv/Fm, and actual photochemical efficiency of PSII (Yield) of two *Ulva* species were decreased under Cd<sup>2+</sup> treatments, and these reductions were greater in *U. prolifera* than in *U. linza*. *U. prolifera* accumulated more cadmium than *U. linza* under Cd<sup>2+</sup> stress. While *U. linza* showed positive osmotic adjustment ability (OAA) at a wider Cd<sup>2+</sup> range than *U. prolifera*. *U. linza* had greater contents of N, P, Na<sup>+</sup>, K<sup>+</sup>, and amino acids than *U. prolifera*. A range of parameters (concentrations of cadmium, Ca<sup>2+</sup>, N, P, K<sup>+</sup>, Cl<sup>-</sup>, free amino acids (FAAs), proline, organic acids and soluble protein, Fv/Fm, Yield, OAA, and K<sup>+</sup>/Na<sup>+</sup>) could be used to evaluate cadmium resistance in *Ulva* by correlation analysis. In accordance with the order of the absolute values of correlation coefficient, contents of Cd<sup>2+</sup> and K<sup>+</sup>, Yield, proline content, Fv/Fm, FAA content, and OAA value of *Ulva* were more highly related to their adaptation to Cd<sup>2+</sup> than the other eight indices. Thus, *U. linza* has a better adaptation to Cd<sup>2+</sup> than *U. prolifera*, which was due mainly to higher nutrient content and stronger OAA and photosynthesis in *U. linza*.

## 1. Introduction

Heavy metal contamination is an environmental problem in the margin sea [1]. As the economy in Asian countries continues to grow, the release of heavy metals and other contaminants has increased noticeably [2, 3]. Due to their acute toxicity, cadmium (Cd), lead, and mercury are among the most hazardous metals to the environment and living things [4].

Cd, an oxophilic and sulfophilic element, forms complexes with various organic particles and thereby triggers a wide range of reactions that collectively put the aquatic ecosystems at risk. Cadmium also poses a serious threat to human health due to its accumulation in the food chain [5, 6]. It has been classified as group (I) a human carcinogen by the International Agency for Research on Cancer (IARC) [7]. Cadmium toxicity may be characterized by a variety of

syndromes and effects, including renal dysfunction, hypertension, hepatic injury, lung damage, and teratogenic effects [8]. To remove Cd pollutants, various treatment technologies, such as precipitation, ion exchange, adsorption, and biosorption, have been employed [9]. Biosorption is one of the promising techniques for removal of heavy metals. Biosorption utilizes the ability of biological materials to accumulate heavy metals from waste streams by either metabolically mediated or purely physicochemical pathways of uptake [10]. Among the biological materials investigated for heavy metal removal, marine macroalgae have high uptake capacities for a number of heavy metal ions [11, 12].

Green algae species of Ulvaceae, especially the members of the green algal genus *Ulva*, have been considered as monitors of heavy metals in estuaries [13–15]. Numerous studies have shown that green macroalgae such as *Ulva lactuca* are able to absorb Cd. These studies mainly focused

on metabolism-independent Cd accumulation [6], synthetic surfactants exerting impact on uptake of Cd [12], effect of pH, contact time, biomass dosage and temperature on the Cd uptake kinetics [2], and induced oxidative stress by Cd [7]. However, little information is available regarding physiological responses of different *Ulva* species to increased Cd<sup>2+</sup> concentrations.

In this study, *Ulva prolifera* and *Ulva linza* were studied for their responses to different Cd<sup>2+</sup> concentrations. Their growth, chlorophyll fluorescence parameters, osmotic adjustment ability, and accumulation of inorganic ions and organic solutes were investigated in indoor seawater culture systems. The specific objective of this study was to determine if there was species variation in Cd<sup>2+</sup> adaptation, and what were the major physiological parameters involved in the adaptation.

## 2. Materials and Methods

**2.1. The Seaweed Collection, Cultivation, and Cd<sup>2+</sup> Treatment.** Green algae were collected from the sea in Dafeng (*Ulva prolifera*) and Lianyungang (*Ulva linza*), Jiangsu province, China. Upon arrival in the laboratory, the seaweeds were washed with distilled water and then cultured in 250 mL flasks containing 200 mL of sterilized artificial seawater (33.33 psu, pH 8.0) enriched with VSE medium [16] for 5 d. The composition of artificial seawater was (g L<sup>-1</sup>) HCO<sub>3</sub><sup>-</sup> 0.25, SO<sub>4</sub><sup>2-</sup> 3.84, Cl<sup>-</sup> 17.45, Ca<sup>2+</sup> 0.76, Mg<sup>2+</sup> 1.00, K<sup>+</sup> 0.57, and Na<sup>+</sup> 9.46. The composition of VSE nutrient solution was (mg L<sup>-1</sup>) NaNO<sub>3</sub> 42.50, Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O 10.75, FeSO<sub>4</sub>·7H<sub>2</sub>O 0.28, MnCl<sub>2</sub>·4H<sub>2</sub>O 0.02, Na<sub>2</sub>EDTA·2H<sub>2</sub>O 3.72, vitamin B<sub>1</sub> 0.20, Biotin 0.001, and vitamin B<sub>12</sub> 0.001. After 5 d acclimation, healthy samples (0.5 g fresh weight) were cultured in 250 mL flasks with 200 mL medium as described earlier. CdCl<sub>2</sub> was added to each flask at the following concentrations: 0, 5, 10, 20, 40, 80, or 120 μmol L<sup>-1</sup>. After 7 d treatment, *U. prolifera* and *U. linza* were harvested and analyzed for selected parameters as described later. All experiments were performed in three replicates. During the preculture and the treatment, seaweeds were grown in a GXZ intelligent light incubator at temperature of 20 ± 1°C, light intensity of 50 μmol m<sup>-2</sup> s<sup>-1</sup>, and photoperiod of 12/12 h. The culture medium was altered every other day.

**2.2. Measurement of Relative Growth Rate (RGR).** Fresh weight was determined by weighing the algae after blotting by absorbent paper. RGR was calculated according to the formula  $RGR (\% d^{-1}) = [\ln(M_t/M_0)/t] \times 100\%$ , where  $M_0$  and  $M_t$  are the fresh weights (g) at days 0 and 7, respectively [17].

**2.3. Measurement of Osmotic Adjustment Ability (OAA).** Saturated osmotic potential was measured by the freezing-point depression principle. Seaweeds were placed in double-distilled water for 8 h and then rinsed 5 times with double-distilled water. After blotting dry with absorbent paper, seaweeds were dipped into liquid nitrogen for 20 min. The frozen seaweeds were thawed in a syringe for 50 min, and the

seaweed sap was then collected by pressing the seaweed in the syringe [18]. The  $\pi_{100}$  was measured by using a fully automatic freezing-point osmometer (8P, Shanghai, China). OAA was calculated by the following equation:

$$\Delta\pi_{100} = \pi_{100}^{\mu} - \pi_{100}^s, \quad (1)$$

whereby  $\pi_{100}^{\mu}$  was the  $\pi_{100}$  of control seaweeds, and  $\pi_{100}^s$  was the  $\pi_{100}$  of Cd<sup>2+</sup>-stressed seaweeds.

**2.4. Measurements of Chlorophyll (Chl) and Carotenoid (Car) Contents.** Determination of Chl and Car was carried out by the method of Häder et al. [19]. Weighed 0.1 g fresh seaweeds were cut with scissors and extracted with 95% (v/v) ethanol (10 mL) in the dark for 24 h. The absorbance of pigment extract was measured at wavelengths of 470, 649, and 665 nm with a spectrophotometer. From the measured absorbance, concentrations of Chl a, Chl b, and Car were calculated on a weight basis.

**2.5. Determination of Chlorophyll Fluorescence Parameters.** A PHYTO-PAM Phytoplankton Analyzer (PAM 2003, Walz, Effeltrich, Germany) was used to determine *in vivo* chlorophyll fluorescence from chlorophyll in photosystem II (PSII) using different experimental protocols [19]. Before determination, samples were adapted for 15 min in the total darkness to complete reoxidation of PSII electron acceptor molecules. The maximal photochemical efficiency of PSII (Fv/Fm) and the actual photochemical efficiency of PSII in the light (Yield) were then determined.

**2.6. Measurement of Nitrogen (N) and Phosphorous (P) Concentrations.** Dried samples were ground in a mortar and pestle. Total N in seaweed tissue was analyzed by an N gas analyzer using an induction furnace and thermal conductivity. Total P in seaweed tissue was quantitatively determined by Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES, Optima 2100 DV, PerkinElmer, USA) following nitric acid/hydrogen peroxide microwave digestion. The total amounts of N and P in the seaweed tissue were calculated by multiplying N and P contents in tissue as a proportion of dry weight by the total dry weight of the sample [20].

**2.7. Measurement of Inorganic Elements.** After 7 d, seaweeds were harvested, washed, and oven-dried at 65°C for 3 d. A 50 mg sample was ashed in a muffle furnace. The ash was dissolved in 8 mL of HNO<sub>3</sub>:HClO<sub>4</sub> (3:1, v:v) and diluted to 50 mL with distilled water. The contents of Cd, Na, K, Ca, and Mg were determined by Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES, Optima 2100 DV, PerkinElmer, USA) [21]. To determine Cl content, the ash was dissolved in 100 mL distilled water and analyzed by potentiometric titration with silver nitrate (AgNO<sub>3</sub>) [18]. Total nitrate was measured as described previously [22] with nitrate extracted from the tissue by boiling fresh seaweeds (20 mg) in distilled water (400 μL) for 20 min. The nitrate concentrations in the samples were measured spectrophotometrically at 540 nm.

**2.8. Measurement of Organic Solutes.** Soluble sugars (SS) determination was carried out by the anthrone method [23]. Water extract of fresh seaweeds was added to 0.5 mL of 0.1 mol L<sup>-1</sup> anthrone-ethyl acetate and 5 mL H<sub>2</sub>SO<sub>4</sub>. The mixture was heated at 100°C for 1 min, and its absorbance at 620 nm was read after cooling to room temperature. A calibration curve with sucrose was used as a standard. Soluble proteins (SPs) were measured by Coomassie Brilliant Blue G-250 staining [24]. Fresh seaweeds (0.5 g) were homogenized in 1 mL phosphate buffer (pH 7.0). The crude homogenate was centrifuged at 5,000 g for 10 min. An aliquot of 0.5 mL of freshly prepared trichloroacetic acid (TCA) was added and mixture centrifuged at 8,000 g for 15 min. The pellets were dissolved in 1 mL of 0.1 mol L<sup>-1</sup> NaOH, and 5 mL of Bradford reagent was added. Absorbance was recorded at 595 nm using bovine serum albumin as a standard. Free amino acids (FAAs) were extracted and determined following the method of Zhou and Yu [23]. A total of 0.5 g fresh tissue was homogenized in 5 mL 10% (w/v) acetic acid, extracts were supplemented with 1 mL distilled water and 3 mL ninhydrin reagent, then boiled for 15 min and fast cooled, and the volume was made up to 5 mL with 60% (v/v) ethanol. Absorbance was read at 570 nm. The content of total free amino acids was calculated from a standard curve prepared using leucine. Proline (PRO) concentration was determined spectrophotometrically by adopting the ninhydrin method of Irigoyen et al. [25]. We first homogenized 300 mg fresh leaf samples in sulphosalicylic acid. To the extract, 2 mL each of ninhydrin and glacial acetic acid were added. The samples were heated at 100°C. The mixture was extracted with toluene, and the free toluene was quantified spectrophotometrically at 528 nm using L-proline as a standard. Organic acids (OAs) were extracted with boiling distilled water. The concentration of total OA was determined by 0.01 mmol L<sup>-1</sup> NaOH titration method, with phenolphthalein as indicator [26].

**2.9. Statistical Analyses.** All experiments were performed in three replicates. The data are presented as the mean ± SD. Data were analyzed using SPSS statistical software. Significant differences between means were determined by Duncan's multiple range test. Unless otherwise stated, differences were considered statistically significant when  $P \leq 0.05$ . Statistical analysis on two-way variance analysis (ANOVA), and correlation coefficient was performed using Microsoft Excel.

### 3. Results

**3.1. Effect of Cadmium Stress on RGR and OAA of *U. prolifera* and *U. linza*.** Compared to the control, treatments with 5  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup> for 7 d did not change RGR of *U. linza*, but significantly decreased RGR of *U. prolifera*. The RGR of both *Ulva* species was significantly decreased as Cd<sup>2+</sup> concentration increased. After 7 d exposure to 10, 20, 40, 80; or 120  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup>, RGR of *U. linza* decreased by 53, 75, 116, 177, and 277%, respectively; *U. prolifera* decreased by 93, 139, 271, and 357%, respectively. *U. prolifera* died at 120  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup> on day 7 (Figure 1).

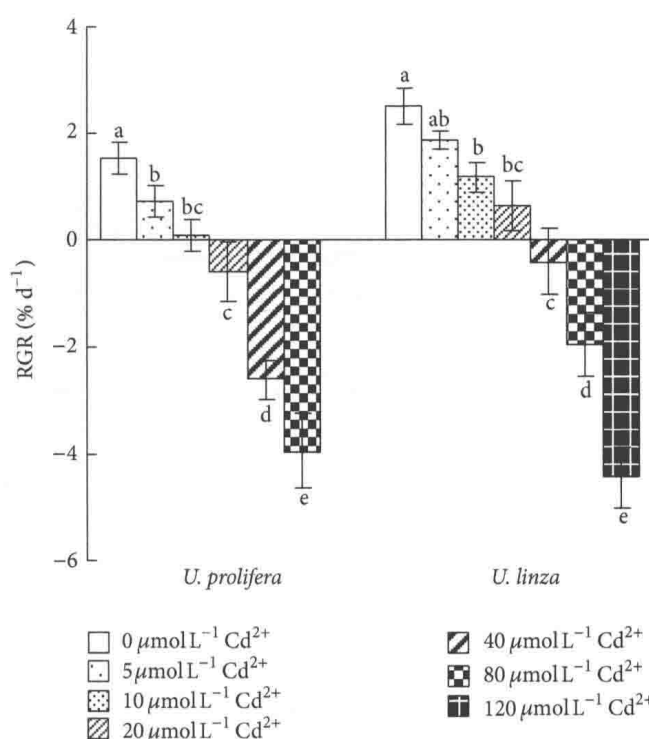

FIGURE 1: Effects of different concentrations of Cd<sup>2+</sup> (0, 5, 10, 20, 40, 80, and 120  $\mu\text{mol L}^{-1}$ ) on relative growth rate (RGR) in *U. prolifera* and *U. linza*.

The OAA of both species was enhanced by low Cd<sup>2+</sup> concentration treatments. The enhancement occurred at 5 and 10  $\mu\text{mol L}^{-1}$  for *U. prolifera* and 5, 10 and 20  $\mu\text{mol L}^{-1}$  for *U. linza* (Figure 2). However, OAA was negative when *U. prolifera* was treated by 20, 40, and 80  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup>, and *U. linza* treated by 40 and 80  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup> (Figure 2).

**3.2. Effect of Cadmium Stress on Cadmium Content in *U. prolifera* and *U. linza*.** Cadmium contents in *U. prolifera* and *U. linza* increased as Cd<sup>2+</sup> concentrations increased (Figure 3). At 5, 10, 20, 40, and 80  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup>, Cd contents in *U. prolifera* was 32, 78, 114, 140, and 165 times of the Cd<sup>2+</sup> = 0 treatment, respectively, and 10, 26, 44, 65, and 79 times of its control treatment in *U. linza*, respectively.

**3.3. Effect of Cadmium Stress on Chl and Car Contents in *U. prolifera* and *U. linza*.** Both Chl and Car contents decreased with the increased Cd<sup>2+</sup> concentration. There was no significant change in Chl and Car when both species were treated by 5 and 10  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup> for 7 d. However, significant declines in Chl and Car contents were observed when they were exposed to 20, 40, or 80  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup>. Compared to the control treatment, Chl contents decreased by 18, 25, and 45% at 20, 40, and 80  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup> in *U. prolifera*, respectively; and the decreases were 16, 20, and 39% in *U. linza*, respectively (Figure 4(a)). The Car content declined by 16, 29 and 54% at 20, 40 and 80  $\mu\text{mol L}^{-1}$  Cd<sup>2+</sup> in *U. prolifera*, respectively; and by 13, 16, and 44% in *U. linza*, respectively (Figure 4(b)).

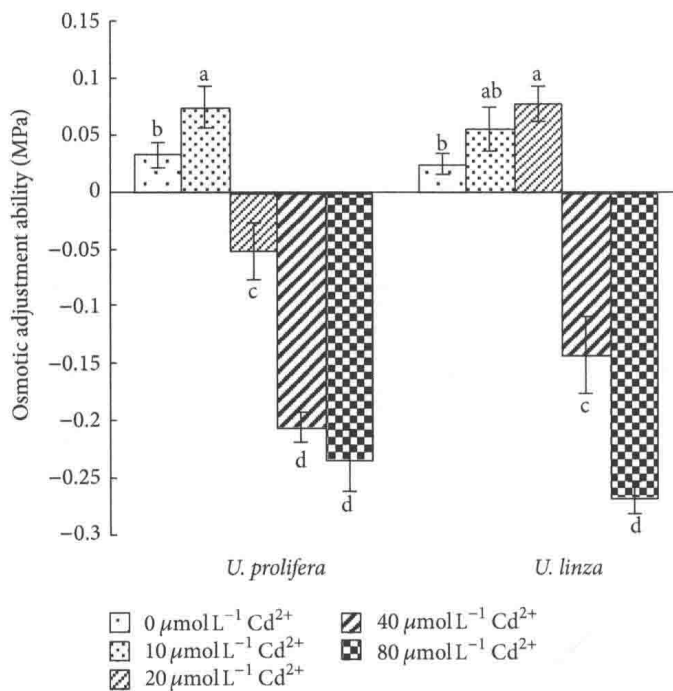

FIGURE 2: Effects of different concentrations of  $\text{Cd}^{2+}$  (5, 10, 20, 40, and 80  $\mu\text{mol L}^{-1}$ ) on osmotic adjustment ability (OAA) of *U. prolifera* and *U. linza*.

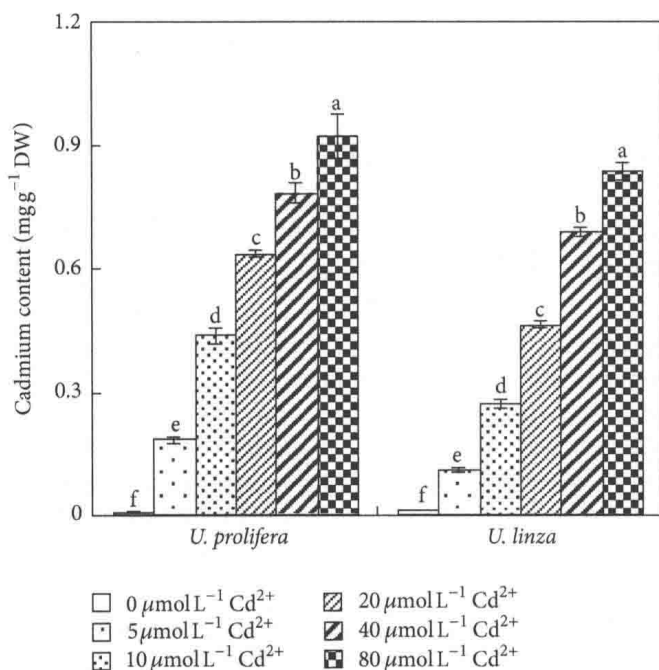

FIGURE 3: Effects of different concentrations of  $\text{Cd}^{2+}$  (0, 5, 10, 20, 40, and 80  $\mu\text{mol L}^{-1}$ ) on cadmium concentration of *U. prolifera* and *U. linza*.

**3.4. Effect of Cadmium Stress on Chlorophyll Fluorescence Parameters of *U. prolifera* and *U. linza*.** Compared to the control treatment, Fv/Fm of *U. prolifera* and *U. linza* were not significantly affected by the treatments of 5 or 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ . However, Fv/Fm of both *Ulva* species fell significantly

when  $\text{Cd}^{2+}$  concentrations reached 20  $\mu\text{mol L}^{-1}$ . In comparison with the control, Fv/Fm of *U. prolifera* decreased 17, 22, and 31% at 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ ; whereas Fv/Fm of *U. linza* decreased 9, 10, and 15% after exposure to 20, 40, or 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , respectively (Figure 5(a)). For actual photochemical efficiency of PSII (Yield) of *U. prolifera*, there was an obvious decrease when  $\text{Cd}^{2+}$  concentrations rose from 20 to 80  $\mu\text{mol L}^{-1}$ ; whereas Yield of *U. linza* showed no significant decline until  $\text{Cd}^{2+}$  concentration was 80  $\mu\text{mol L}^{-1}$  (Figure 5(b)).

**3.5. Effect of Cadmium Stress on Contents of N and P in *U. prolifera* and *U. linza*.** Contents of N and P in both *Ulva* species showed a declining trend after an initial increase. The highest N content was recorded at 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  in *U. prolifera* and at 20  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  in *U. linza*. N contents in *U. linza* in all  $\text{Cd}^{2+}$  treatments were higher than those of control; however, in *U. prolifera*, N contents at 20, 40, or 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  were significantly decreased compared to the control (Figure 6(a)).

*U. prolifera* had the highest P concentration at 5  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ ; but the highest P concentration was observed when *U. linza* was treated by 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ . The P contents decreased 31, 40, and 54% at 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  in *U. prolifera*, respectively. Compared to the control, the P concentration of *U. linza* at 20  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  increased significantly, and then decreased by 11 and 27% under 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , respectively (Figure 6(b)).

**3.6. Effect of Cadmium Stress on Inorganic Elements of *U. prolifera* and *U. linza*.** The  $\text{Na}^{+}$  content of *U. prolifera* grown at 5 or 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  was not significantly different from the control, and it increased by 42, 67, and 83% at 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , respectively. However, in *U. linza*, 5, 10, 20, and 40  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  had no significant influence on  $\text{Na}^{+}$  content, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  increased  $\text{Na}^{+}$  content by 36% (Table 1). The  $\text{K}^{+}$  content of *U. prolifera* grown at 5 or 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  remained unaffected compared to the control; it decreased significantly by 41, 45, and 62% at 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , respectively. In *U. linza*, 5, 10, and 20  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  had no significant influence on  $\text{K}^{+}$  content, whereas 40 and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  decreased  $\text{K}^{+}$  content by 34 and 50%, respectively (Table 1). The  $\text{Ca}^{2+}$  content of *U. prolifera* grown at 5, 10, 20, or 40  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  remained unaffected, but increased significantly (24%) at 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ . However, in *U. linza*, 5 and 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  had no significant influence on  $\text{Ca}^{2+}$  contents, whereas 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  increased  $\text{Ca}^{2+}$  content by 22, 39, and 50%, respectively (Table 1). The  $\text{Mg}^{2+}$  content of *U. prolifera* grown at 5, 10, 20, 40 or 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  remained unaffected. With increasing  $\text{Cd}^{2+}$  concentrations,  $\text{Mg}^{2+}$  contents of *U. linza* showed an increasing trend after an initial decline (Table 1). The  $\text{Cl}^{-}$  contents appeared to have a declining trend with increasing  $\text{Cd}^{2+}$  concentration similarly to Mg concentrations. However, no obvious difference in  $\text{Cl}^{-}$

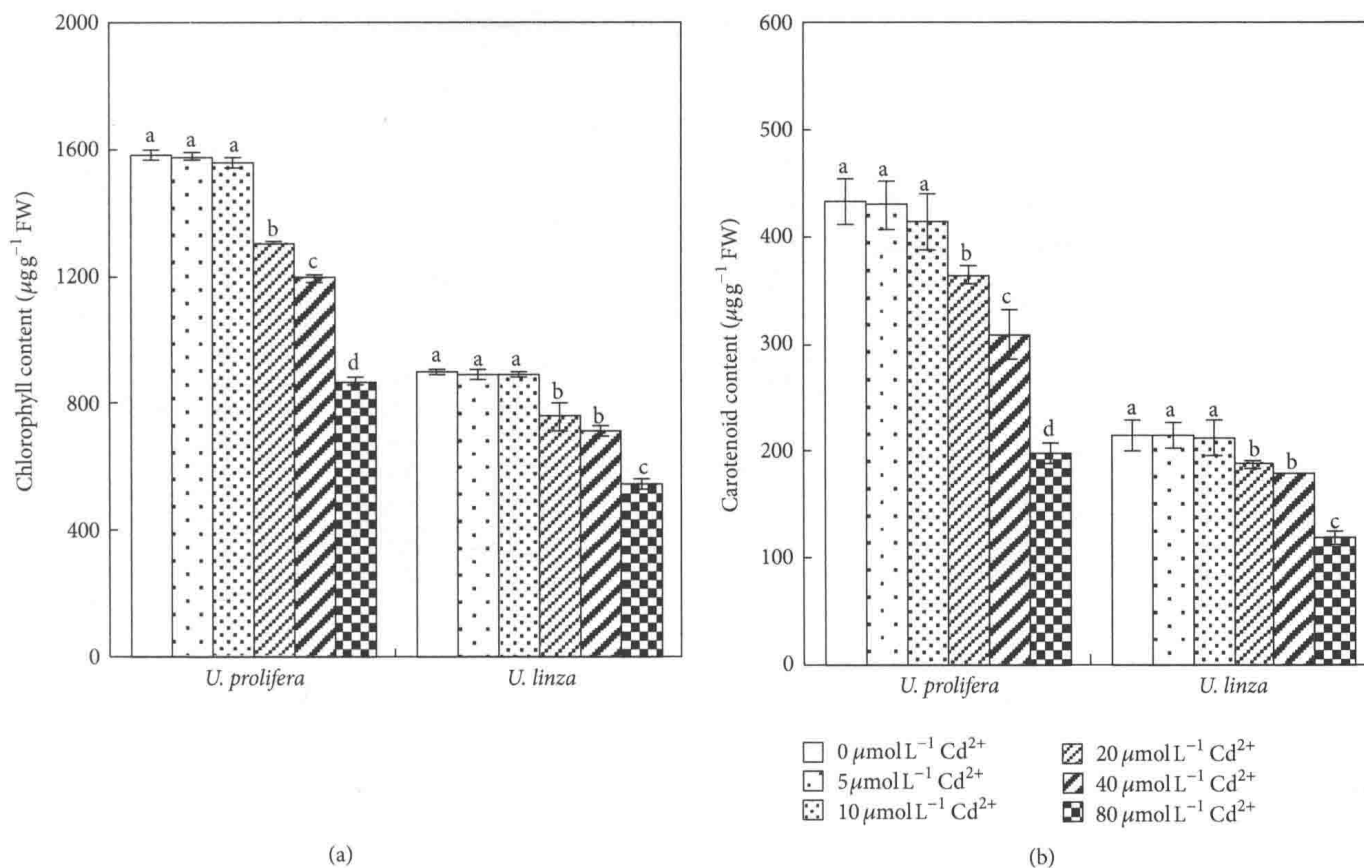

FIGURE 4: Effects of different concentrations of  $\text{Cd}^{2+}$  (0, 5, 10, 20, 40, and 80  $\mu\text{mol L}^{-1}$ ) on chlorophyll content (a) and carotenoid content (b) in *U. prolifera* and *U. linza*.

contents among all  $\text{Cd}^{2+}$  treatments was noted in the two *Ulva* species (Table 1). Nitrate content in *U. prolifera* showed an uptrend with increasing  $\text{Cd}^{2+}$  concentration; however, with increasing  $\text{Cd}^{2+}$  concentrations, nitrate content of *U. linza* showed a decline trend after an initial increase. We also found that nitrate contents of *U. linza* were much more than those of *U. prolifera* under all treatments except for 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  treatment (Table 1).

The  $\text{K}^+/\text{Na}^+$  and  $\text{Ca}^{2+}/\text{Na}^+$  ratios in *U. prolifera* were not influenced by 5 and 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , but they showed declining trends at 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  (Table 1). In *U. linza*, 5 and 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  had no significant influence on the  $\text{K}^+/\text{Na}^+$  ratio, whereas 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  decreased that ratio by 6, 45, and 64%, respectively. However, in *U. prolifera*, 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  decreased the  $\text{K}^+/\text{Na}^+$  ratio by 55, 65, and 78%. No  $\text{Cd}^{2+}$  treatment significantly changed the  $\text{Ca}^{2+}/\text{Na}^+$  ratio in *U. linza*.

**3.7. Effect of Cadmium Stress on Organic Solutes in *U. prolifera* and *U. linza*.** With increasing  $\text{Cd}^{2+}$  concentration, soluble sugar (SS) content appeared to have an ascending trend after an initial decline in both *Ulva* species. In *U. prolifera*, 40  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  did not change the SS content, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  increased SS concentration by 27% compared to the control. However, in *U. linza*, 40 and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  increased SS content by 40 and 90%, respectively

(Table 2). In *U. prolifera* and *U. linza*, 5  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  significantly increased free amino acid (FAA) content by 25 and 16%, respectively. However, 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  had no obvious change on FAA contents of the two *Ulva* species. Treatments with 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  significantly decreased FAA content by 52, 79, and 87% in *U. prolifera* and by 2, 25, and 43% in *U. linza* (Table 2). Proline (PRO) content was greatly enhanced by  $\text{Cd}^{2+}$  treatments in both *Ulva* species. At 5, 10, 20, 40, and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , PRO content was increased 154, 431, 715, 1031, and 1069%, respectively, in *U. prolifera*; and increased 147, 420, 726, 1040, and 1147%, respectively, in *U. linza* (Table 2). Organic acid (OA) content in *U. prolifera* was not affected at 5, 10 and 20  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , and OA concentration in *U. linza* was not affected at 5, 10, 20, and 40  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ . Treatments with 40 and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  decreased OA content by 29 and 47%, respectively, in *U. prolifera*, whereas in *U. linza* only 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  decreased OA content by 27% (Table 2). The soluble protein (SP) content in the two *Ulva* species was not affected at 5, 10 and 20  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  and was decreased at 40 and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ . Treatments with 40 and 80  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  significantly decreased SP content by, respectively, 16 and 42% in *U. prolifera* and by 8 and 25% in *U. linza* (Table 2).

**3.8. Correlation Analysis between RGR and Other Physiological and Biochemical Indexes under Cadmium Stress.** Correlation

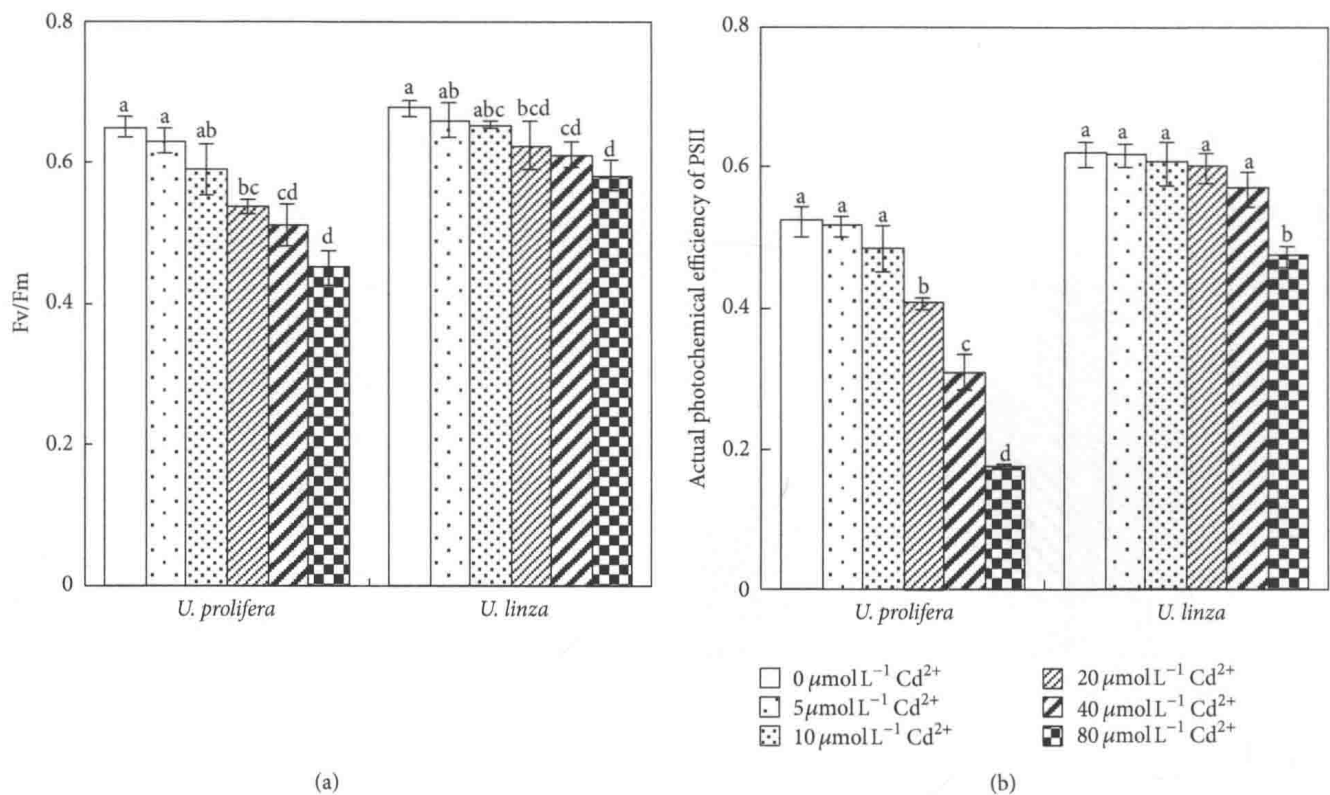

FIGURE 5: Effects of different concentrations of  $\text{Cd}^{2+}$  (0, 5, 10, 30, 40, and 80  $\mu\text{mol L}^{-1}$ ) on  $\text{Fv/Fm}$  (a) and Yield (actual photochemical efficiency of PSII) (b) of *U. prolifera* and *U. linza*.

analysis indicated that RGR of both *Ulva* species was insignificantly related to contents of Chl, Car,  $\text{Na}^+$  and  $\text{Mg}^{2+}$ , and the  $\text{Ca}^{2+}/\text{Na}^+$  ratio. In contrast, RGR was highly negative correlated with the contents of  $\text{Cd}^{2+}$ ,  $\text{Ca}^{2+}$ , SS, and PRO, and highly positive correlated with the contents of N, P, K, Cl, FAA, OA and SP,  $\text{K}^+/\text{Na}^+$  ratio, OAA,  $\text{Fv/Fm}$ , and Yield (Table 3).

#### 4. Discussion

Plant growth can be suppressed by Cd [7, 17]. It was reported that *Ulva lactuca* was sensitive to cadmium, as obviously shown by growth reduction and lethal effects at 40  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  within 6 days [27]. In the study presented here, *U. prolifera* and *U. linza*, the dominant free-floating *Ulva* species of green tide bloom in the Yellow Sea of China [28], showed sensitivity to  $\text{Cd}^{2+}$  (reduction in RGR,  $\text{Fv/Fm}$ , and Yield). Furthermore, this reduction was found to be more pronounced in *U. prolifera* than *U. linza*. After 7 d, *U. prolifera* died at 120  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , whereas *U. linza* was still alive (Figures 1 and 4). This result indicated that *U. linza* had better adaptation to  $\text{Cd}^{2+}$  toxicity than *U. prolifera*.

It is known that marine macroalgae can concentrate heavy metals to a large extent [2, 29]. In this study, Cd accumulation in *U. prolifera* and *U. linza* increased significantly in response to increased  $\text{Cd}^{2+}$  concentrations. However, *U. prolifera* accumulated more Cd than *U. linza* (Figure 3). In general, plant accumulation of a given metal

is a function of uptake capacity and intracellular binding sites [30]. The cell walls of plant cells contain proteins and different carbohydrates that can bind metal ions. After the binding sites in the cell wall become saturated, intracellular Cd accumulation mediated by metabolic processes may lead to cell toxicity [31].

*Ulva* species are widely distributed in the coastal intertidal zones where had full change on salinity level. Thus, many *Ulva* species have strong OAA to cope with variable and heterogeneous environments. Similarly to a number of other stresses, heavy metal toxicity can decrease cell water content and lower the cell water potential ( $\psi_w$ ) through increased net concentrations of solutes (osmotic adjustment), which is a common response to water stress and an important mechanism for maintaining cell water content and, thus, turgor [18, 32]. In our experiments, OAA of *U. linza* had positive values in the treatments with 5, 10, or 20  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$ , whereas *U. prolifera* had positive OAA only at 5 and 10  $\mu\text{mol L}^{-1}$   $\text{Cd}^{2+}$  (Figure 2). When OAA values in *Ulva* were positive, that is, OAA contributed to maintaining turgor, *Ulva* could continue growing, and RGR was positive. However, when OAA in *Ulva* was negative resulting in turgor loss, the growth was stopped, and RGR was negative. Correlation analysis also showed that RGR was positively related to OAA, suggesting that OAA played an important role in maintaining algal growth. Also, good osmotic adjustment enabled plants to maintain high photosynthetic activity (Figure 5).

Cadmium is a nonessential element for plant growth, and it inhibits uptake and transport of many macro- and

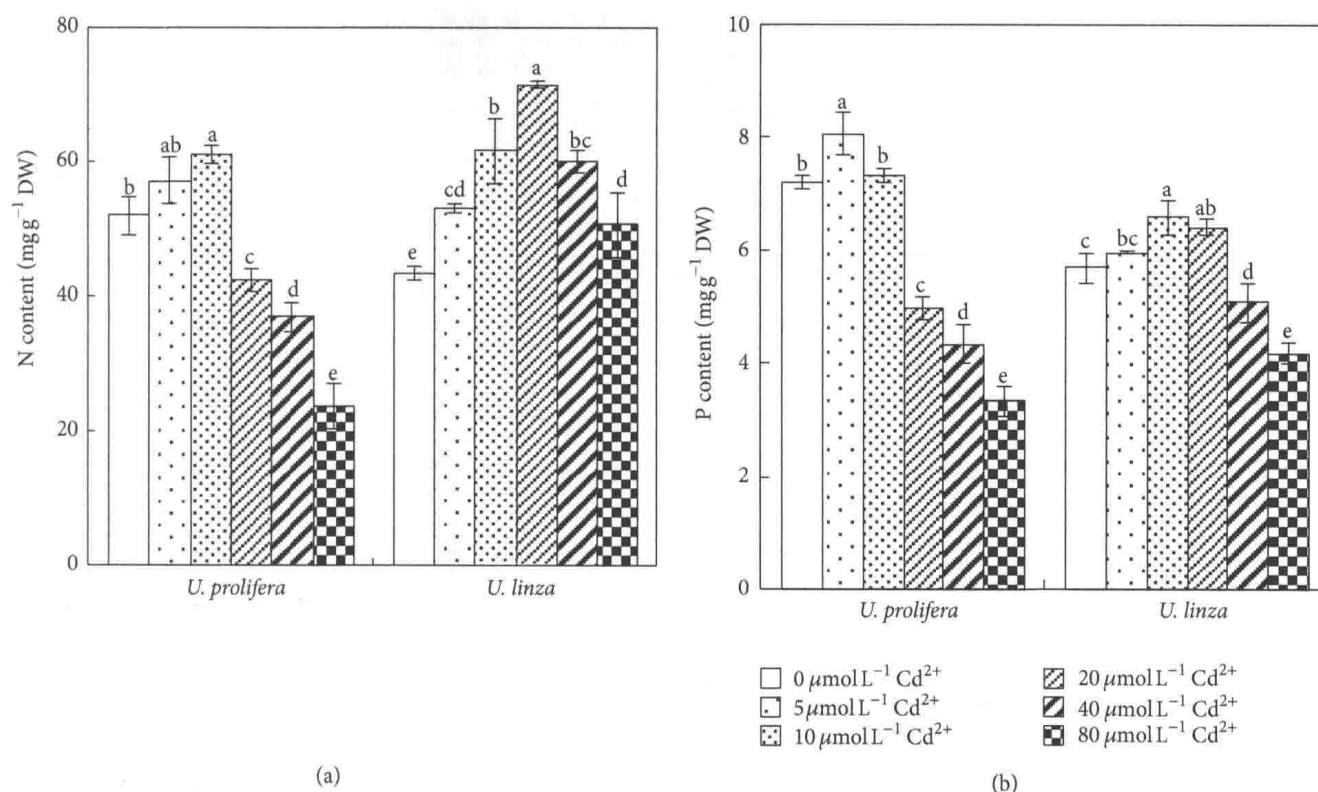

FIGURE 6: Effects of different concentrations of  $\text{Cd}^{2+}$  (0, 5, 10, 20, 40, 80  $\mu\text{mol L}^{-1}$ ) on contents of N (a) and P (b) of *U. prolifera* and *U. linza*.

micronutrients, inducing nutrient deficiency [7, 17]. Contradictory data can be found in the literature on the effects exerted by  $\text{Cd}^{2+}$  on terrestrial plant. Cadmium was reported to reduce uptake of N, P, K, Ca, Mg, Fe, Zn, Cu, Mn, Ni, and Na in many crop plants [33], whereas other authors found reduced K uptake but unchanged P uptake or even an increase in K content of several crop varieties under  $\text{Cd}^{2+}$  stress [34, 35]. Obata and Umebayashi [36] reported that  $\text{Cd}^{2+}$  treatment increased Cu content in the roots of pea, rice, and maize, but unchanged Cu content in cucumber and pumpkin plants. With  $\text{Cd}^{2+}$  stress, Maksimović et al. [37] observed a reduction in the maize root influx and root-shoot transport of Cu, Zn, and Mn, a reduction in the root-shoot transport of Fe, but an increase in Fe influx and Ca and Mg transport. In this study, the response of total N and P concentrations in tissues of the two *Ulva* species to  $\text{Cd}^{2+}$  treatments was positively related to their Cd resistance. We found that the treatment with low concentration of  $\text{Cd}^{2+}$  enhanced N and P contents, but high concentrations of  $\text{Cd}^{2+}$  ( $\geq 20 \mu\text{mol L}^{-1}$ ) decreased N and P contents in both *Ulva* species. The maintenance of total N and total P was more pronounced in less Cd-sensitive *U. linza* than Cd-sensitive *U. prolifera* (Figure 6). This suggests that the maintenance of a normal level of total N content upon challenge with Cd is likely to be a feature in relative Cd-resistant marine macroalgae, similarly to terrestrial plants [38]. In *Ulva*, we found that the contents of  $\text{K}^+$ ,  $\text{Ca}^{2+}$ , and  $\text{Cl}^-$  were related to RGR, especially  $\text{K}^+$  reduction caused *Ulva* growth reduction significantly (Table 1). Thus, the  $\text{K}^+/\text{Na}^+$  ratio in both *Ulva* species decreased significantly with increasing  $\text{Cd}^{2+}$  treatment concentrations, and

$\text{Cd}^{2+}$ -sensitive *U. prolifera* showed a greater  $\text{K}^+/\text{Na}^+$  decline than  $\text{Cd}^{2+}$ -sensitive *U. linza* (Table 1).

We measured a decline in soluble sugar (SS) concentration at low  $\text{Cd}^{2+}$  treatment concentrations and an increase at high  $\text{Cd}^{2+}$  concentrations in both *Ulva* species. Moreover, the SS increase of *U. linza* is more marked than that of *U. prolifera*. In other studies, the decline in SS concentration corresponded with the photosynthetic inhibition or stimulation of respiration rate, affecting carbon metabolism and leading to production of other osmotica [39]. The accumulating soluble sugars in plants growing in presence of  $\text{Cd}^{2+}$  could provide an adaptive mechanism via maintaining a favorable osmotic potential under adverse conditions of  $\text{Cd}^{2+}$  toxicity [40].

Soluble protein (SP) content in organisms is an important indicator of metabolic changes and responds to a wide variety of stresses [41]. In this work, SP contents in *U. prolifera* and *U. linza* declined with increasing  $\text{Cd}^{2+}$  treatment concentrations. Free amino acid (FAA) contents in both *Ulva* species first increased and then declined, with such a decline more pronounced in *U. prolifera* than in *U. linza*. The decreased protein content together with the increased free amino acid content suggest that the protein synthesizing machinery was impaired due to the  $\text{Cd}^{2+}$  effect [42].

PRO accumulation in plant tissues in response to a number of stresses, including drought, salinity, extreme temperatures, ultraviolet radiation, or heavy metals, is well documented [43]. In this study, even though PRO content was increased in  $\text{Cd}^{2+}$ -treated *Ulva*, its absolute amount was relatively low. Under assumed localization of inorganic ions

TABLE 1: Effects of different concentrations of  $\text{Cd}^{2+}$  (0, 5, 10, 30, 40, and 80  $\mu\text{mol L}^{-1}$ ) on inorganic ion content ( $\text{mmol g}^{-1}$  DW),  $\text{K}^+/\text{Na}^+$  and  $\text{Ca}^{2+}/\text{Na}^+$  of *U. prolifera* and *U. linza*.

\*Significant at 5% level, \*\* significant at 1% level (two-tailed,  $n = 18$ ).

in the vacuole and organic solutes in the cytoplasm, FAA and PRO may be mainly in the cytoplasm, accounting for about 5%–10% volume in mature cells [44]. A small amount of FAA and PRO accumulating in the cytoplasm can increase concentration significantly and play an important role in balancing vacuolar osmotic potential [44]. It has often been suggested that PRO accumulation may contribute to osmotic adjustment at the cellular level [39]. In addition, PRO as a

compatible solute may protect enzymes from dehydration and inactivation [18].

In conclusion, exposing *U. prolifera* and *U. linza* to different concentrations of  $\text{Cd}^{2+}$  resulted in the changes in growth, pigment content, chlorophyll fluorescence parameters, Cd accumulation, OAA, and concentration of N, P, main inorganic ions, and organic solutes. These changes make *U. linza* better adapted to withstanding  $\text{Cd}^{2+}$  stress in comparison with *U. prolifera*. Our results highlight the role of osmotic adjustment in *Ulva* during  $\text{Cd}^{2+}$  stress as an important mechanism enabling *Ulva* to maintain photosynthetic activity and, thus, growth under  $\text{Cd}^{2+}$  stress.

## Authors' Contribution

H. Jiang and B. Gao both contributed equally to this paper.

## Acknowledgments

The authors thank professor Zed Rengel, University of Western Australia, for his helpful comments on this study. Also, they thank professor Jianjun Chen, University of Florida, for his good revision on this paper. This work was supported by Open Foundation of Key Laboratory of Exploitation and Preservation of Coastal Bio-resources of Zhejiang Province (2010F30003), the National Key Project of Scientific and Technical Supporting Programs funded by Ministry of Science and Technology of China (no. 2009BADA3 B04-8). The authors also acknowledge members of our laboratory for assistance in this work.
