**ASM
PRESS**

WASHINGTON, D.C.

Cover photograph (courtesy of Richard Losick and Masaya Fujita, Department of Molecular and Cellular Biology, Harvard University) illustrates the cellular localization of a Bacillus subtilis sporulation-specific transcription factor, σ^E , as visualized with protein fusions to the "green fluorescent protein." Pro- σ^E first localizes to the septal and cytoplasmic membranes of sporulating cells at the stage of polar septation as shown in the cells on the right side of the insert. To the left, the mature σ^E is present in the cytoplasm in the large chamber of the sporangium, where it directs mother-cell-specific transcription.

SECOND EDITION

**Molecular Genetics
of Bacteria**

Preface

We were motivated to prepare a second edition of our textbook *Molecular Genetics of Bacteria* because of the favorable response to the first edition and because of the important advances made in this field since the original edition was published. The second edition retains much of the organization and style of the first edition. The order of topics is unchanged as is the emphasis on experimental approaches: features popular with most instructors using the first edition. Each chapter retains a chapter summary, problems (with answers), and suggested readings, all of which are updated. We continue to use “boxes” to present material of related interest to each topic without breaking the continuity of the narrative. The material in these boxes can serve as a starting point for special reports or to link with material from other courses that the students might be taking. One change in the organization of the second edition is that much of the material in the last four chapters of the first edition, which presented some more sophisticated experiments and some current applications, has been updated and incorporated into the earlier chapters. As a result, the chapters usually begin with a descriptive treatment of each topic and end with some relatively technical molecular genetic experiments that led to the knowledge. This organization allows instructors to assign only early sections of each chapter if appropriate but retains the usefulness of the textbook for more advanced undergraduate and beginning graduate classes. This allows the book to be more concise since each subject need be introduced only once. We added a final chapter that illustrates comprehensively how the techniques and concepts of bacterial molecular genetics discussed in earlier chapters have been used to study biological phenomena such as protein translocation and sporulation.

The material in each chapter is substantially updated and reflects the exciting developments in the field of bacterial molecular genetics and emphasizes the relationships of prokaryotic and eukaryotic cell biology and

development. In particular, important progress has been made since the first edition in understanding chromosome segregation and cell division in bacteria; the close relationship of protein secretion and conjugation both between bacteria and from bacteria into eukaryotes; the intimate relationship between the “three Rs”—replication, recombination, and repair; the universality of repair mechanisms and mutagenic DNA polymerases and their roles in cancer; the techniques of genomics, microarrays, and bioinformatics and their applications in bacterial molecular genetics; as well as many other important updates. With these changes, the textbook will continue to provide an appropriate up-to-date treatment of bacterial molecular genetics for undergraduate and beginning graduate courses and will also continue to provide a good foundation and reference guide for scientists in the many fields of biology and engineering who depend on the concepts and techniques developed with prokaryotes.

An extraordinary number of researchers have made major contributions to the field of bacterial molecular genetics. We could not reasonably expect students to learn even a fraction of their names, and we could not possibly do justice to all of their important contributions. Therefore, we include only those names that have become icons in the field because they are associated with certain seminal experiments (e.g., Meselson and Stahl or Luria and Delbrück), models (e.g., Jacob and Monod), or a structure (e.g., Watson and Crick). We redress our omissions somewhat in the suggested readings, where we give some of the original references to the developments under discussion.

In writing the second edition, we have benefited from the help and advice of a large number of colleagues around the world. Many instructors using the first edition pointed out errors and communicated advice. Many additional colleagues generously read or discussed material in their areas of specialty. We would particularly like to thank our colleague at Michigan State University, Lee Kroos, for his careful reading of the new *Bacillus subtilis* sporulation section. We also benefited from the input of many of our own undergraduates, who used the first edition in our classes. We especially thank Andrea Hartlerode and Heather Hall, who pointed out areas they found confusing or in need of additional explanation. However, we take full responsibility for any mistakes, misconceptions, or omissions.

As before, it was a great pleasure to work with the professionals at ASM Press, who repeated their magic act of transforming our primitive text and illustrations into a printed book. For the first edition, as neophyte authors, we depended on the expert advice of the former director of ASM Press, Patrick Fitzgerald. In preparing the second edition, we have been indebted to the current director, Jeff Holtmeier, for his encouragement, enthusiasm, and patience. We have also had the good fortune to work again with a number of the same professionals who did a masterful job with the first edition, including Susan Birch, Production Manager, who oversaw the entire process; Yvonne Strong, who copyedited the manuscript and illustrations; Susan Brown Schmidler, who created the book and cover design; and Terese Winslow, who created the cover illustration. Finally, we especially thank Berta Steiner, president of Bermedica Production, Ltd., who managed this publication project and supervised the work of Precision Graphics artists who rendered our hand-drawn sketches into clear attractive figures.

Phage Genetics 7

Phages Are Haploid 7

Selections with Phages 7

Crosses with Phages 7

A Brief History of Bacterial Molecular Genetics 7

- Inheritance in Bacteria 8
- Transformation 8
- Conjugation 8
- Transduction 8
- Recombination within Genes 8
- Semiconservative DNA Replication 9
- mRNA 9
- Genetic Code 9
- The Operon Model 9
- Enzymes for Molecular Biology 9

What's Ahead 9

SUGGESTED READING 10

PART I

Genes: Replication and Expression 11

CHAPTER 1

Macromolecular Synthesis: Chromosome Structure, Replication, and Segregation 13

DNA Structure 13

- The Deoxyribonucleotides 13
- The DNA Chain 14
- The 5' and 3' Ends 14
- Base Pairing 14
- Antiparallel Construction 16
- The Major and Minor Grooves 16

Mechanism of DNA Replication 17

- Deoxyribonucleotide Precursor Synthesis 17
- Deoxynucleotide Polymerization 17
- Semiconservative Replication 19
- Replication of Double-Stranded DNA 21

Replication Errors 24

- Editing 26
- Methyl-Directed Mismatch Repair 27
- Role of Editing and Mismatch Repair in Maintaining Replication Fidelity 27

Replication of the Bacterial Chromosome and Cell Division 28

- Structure of the Bacterial Chromosome 28
- Replication of the Bacterial Chromosome 29
- Initiation of Chromosome Replication 29

- Termination of Chromosome Replication 30
- Segregation of the Two Daughter DNAs after Replication 32
- Partitioning of the Chromosome after Replication 35
- Where Are the Replication Forks? 37
- Cell Division 37
- Coordination of Cell Division with Replication of the Chromosome 38
- Timing of Initiation of Replication 40

Supercoiling 41

- The Bacterial Nucleoid 41
- Supercoiling in the Nucleoid 42
- Topoisomerases 43

Antibiotics That Affect Replication and DNA Structure 45

- Antibiotics That Block Precursor Synthesis 45
- Antibiotics That Block Polymerization of Nucleotides 45
- Antibiotics That Affect DNA Structure 46
- Antibiotics That Affect Gyrase 46

Molecular Biology Manipulations with DNA 46

- Restriction Endonucleases 46
- Hybridizations 49
- Applications of the Enzymes Used in DNA Replication 52

SUMMARY 58

QUESTIONS FOR THOUGHT 59

PROBLEMS 59

SUGGESTED READING 60

CHAPTER 2

Macromolecular Synthesis: Gene Expression 61

Overview 61

The Structure and Function of RNA 62

- Types of RNA 62
- RNA Precursors 62
- RNA Structure 63
- RNA Processing and Modification 65

Transcription 65

- Bacterial RNA Polymerase 65
- Transcription Initiation 65
- The Polymerization Reaction 68
- Transcription Termination 70
- rRNAs and tRNAs and Their Synthesis 72

Proteins 73

- Protein Structure 73
- Translation 75
- Details of Protein Synthesis 75
- The Genetic Code 81
- Translation Initiation 83
- Translation Termination 86
- Polycistronic mRNA 86

Protein Folding 89

- Chaperones 89
- Membrane Proteins and Protein Export 91
- The Targeting Factors 91
- Protein Secretion 93
- Disulfide Bonds 94
- Regulation of Gene Expression 94

Useful Concepts 97

- Open Reading Frame 99
- Transcriptional and Translational Fusions 100

Antibiotics That Block Transcription and Translation 102

- Antibiotic Inhibitors of Transcription 102
- Antibiotic Inhibitors of Translation 103
- SUMMARY 106
- QUESTIONS FOR THOUGHT 108
- PROBLEMS 108
- SUGGESTED READING 109

PART II**Genes and Genetic Elements 111****CHAPTER 3****Mutations and Genetic Analysis 113****Definitions 113**

- Terms Used in Genetics 113
- Genetic Names 114

Useful Phenotypes in Bacterial Genetics 115

- Auxotrophic Mutants 115
- Conditional Lethal Mutants 116
- Resistant Mutants 117

Inheritance in Bacteria 117

- The Luria and Delbrück Experiment 118
- The Newcombe Experiment 121
- The Lederbergs' Experiment 123

Mutation Rates 123

- Calculating Mutation Rates 123
- Using the Increase in the Fraction of Mutants To Measure Mutation Rates 125
- Summary 126

Types of Mutations 126

- Base Pair Changes 127
- Frameshift Mutations 131
- Deletion Mutations 132
- Inversion Mutations 133
- Tandem Duplication Mutations 135
- Insertion Mutations 135

Reversion versus Suppression 136

- Intragenic Suppressors 136
- Intergenic Suppressors 136
- Nonsense Suppressors 137

Genetic Analysis 139

- Isolating Mutants 140
- Isolating Independent Mutations 140
- Selecting Mutants 141
- Replica Plating 142
- Enrichment 142
- Complementation 143
- Recombination Tests 145
- Gene Replacements and Transgenics 148
- SUMMARY 154
- QUESTIONS FOR THOUGHT 155
- PROBLEMS 155
- SUGGESTED READING 156

CHAPTER 4**Plasmids 157****What Is a Plasmid? 157**

- Naming Plasmids 157
- Functions Encoded by Plasmids 159
- Plasmid Structure 159

Properties of Plasmids 161

- Replication 161
- Functions of the *ori* Region 165
- Mechanisms To Prevent Curing of Plasmids 172
- The *par* Systems 174
- Incompatibility 176
- Maintaining Plasmids Belonging to the Same Incompatibility Group 178

Constructing a Plasmid Cloning Vector 179Finding the Plasmid *ori* Region 179

Examples of Plasmid Cloning Vectors 180

Broad-Host-Range Cloning Vectors 183

SUMMARY 184

QUESTIONS FOR THOUGHT 185

PROBLEMS 185

SUGGESTED READING 185

CHAPTER 5**Conjugation 187****Overview 187**

Classification of Self-Transmissible Plasmids 188

Interspecies Transfer of Plasmids 188

Mechanism of DNA Transfer during Conjugation in Gram-Negative Bacteria 189Transfer (*tra*) Genes 192The *oriT* Sequence 197

Efficiency of Transfer 197

Mobilizable Plasmids 198

Chromosome Transfer by Plasmids 201

Formation of Hfr Strains 202

Transfer of Chromosomal DNA by Integrated Plasmids 202

Genetic Mapping with Hfr Crosses 204

Genetic Markers 204

Analysis of Hfr Crosses 205

Chromosome Mobilization 207**Prime Factors 207**

Creation of Prime Factors 208

Complementation Tests Using Prime Factors 208

Role of Prime Factors in Evolution 210

Transfer Systems of Gram-Positive Bacteria 210

Plasmid-Attracting Pheromones 210

Other Types of Transmissible Elements 214

SUMMARY 214

QUESTIONS FOR THOUGHT 215

PROBLEMS 215

SUGGESTED READING 216

CHAPTER 6**Transformation 217****Natural Transformation 217**

Discovery of Transformation 218

Competence 218

Uptake of DNA during Natural Transformation 221

Mechanism of DNA Uptake
during Transformation 222

Genetic Evidence for Single-Strand Uptake 223

Plasmid Transformation and Transfection
of Naturally Competent Bacteria 223

The Role of Natural Transformation 224

Artificially Induced Competence 226

Calcium Ion Induction 226

Electroporation 228

SUMMARY 228

QUESTIONS FOR THOUGHT 229

PROBLEMS 229

SUGGESTED READING 229

CHAPTER 7**Lytic Bacteriophages: Genetic Analysis and Use in Transduction 231****Bacteriophage Lytic Development Cycle 233**

Phage T7: a Phage-Encoded RNA Polymerase 234

Phage T4: Transcriptional Activators, Antitermination,
a New Sigma Factor, and Replication-Coupled
Transcription 237**Phage DNA Replication 242**

Phages with Single-Stranded Circular DNA 243

Phage T7: Linear DNA
That Forms Concatemers 249Phage T4: Another Linear DNA
That Forms Concatemers 250**Genetic Analysis of Phages 252**

Infection of Cells 253

Phage Crosses 253

Recombination and Complementation
Tests with Phages 254Experiments with the *rII* Genes of Phage T4 256Constructing the Genetic Linkage Map
of a Phage 263

Generalized Transduction 267

- What Makes a Transducing Phage? 268
- Mapping of Bacterial Markers by Transduction 269
- The Role of Transduction in Bacterial Evolution 272

SUMMARY 272

QUESTIONS FOR THOUGHT 273

PROBLEMS 273

SUGGESTED READING 274

CHAPTER 8**Phage λ and Lysogeny 275****Phage λ 276**

- Phage λ : Lytic Development 276
- Phage λ : Linear DNA
That Replicates as a Circle 281

Lysogeny 282

- The *cII* Gene Product 282
- Phage λ Integration 283
- Maintenance of Lysogeny 285
- Regulation of Repressor Synthesis
in the Lysogenic State 285
- Immunity to Superinfection 286
- The Induction of λ 286
- Competition between the Lytic
and Lysogenic Cycles 287

Specialized Transduction 290**Other Lysogenic Phages 291**

- Phage P2 291
- Phage P4 291
- Phage P1: a Plasmid Prophage 293
- Phage Mu 294
- Use of Lysogenic Phages as Cloning Vectors 294

Lysogenic Phages and Bacterial Pathogenesis 294

- E. coli* and Dysentery: Shiga Toxins 294
- Diphtheria 295
- Cholera 295
- Botulism and Tetanus 296
- Synopsis 296

Genetic Experiments with Phage λ 296

- Genetics of λ Lysogeny 296
- Genetics of the *CI* Repressor 297
- Isolation of λ *nut* Mutations 297
- Isolation of Host *nus* Mutations 300

SUMMARY 300

QUESTIONS FOR THOUGHT 301

PROBLEMS 302

SUGGESTED READING 302

CHAPTER 9**Transposition and Site-Specific Recombination 303****Transposition 303**

- Overview of Transposition 304
- Structure of Bacterial Transposons 304
- Types of Bacterial Transposons 305
- Assays of Transposition 308
- Genetic Requirements for Transposition 310
- Molecular Models for Transposition 314

Transposon Mutagenesis 319

- Transposon Mutagenesis of Plasmids 320
- Transposon Mutagenesis
of the Bacterial Chromosome 325
- Transposon Mutagenesis of All Bacteria 328
- Using Transposon Mutagenesis To Make Random
Gene Fusions 329
- In Vivo Cloning 332

Site-Specific Recombination 333

- Developmentally Regulated Excision
of Intervening DNA 333
- Integrases 334
- Resolvases 336
- DNA Invertases 336
- Topoisomerases 338

SUMMARY 338

Introduction

THE GOAL OF THIS TEXTBOOK is to introduce the student to the field of bacterial molecular genetics. Bacteria are relatively simple organisms, and some are quite easy to manipulate in the laboratory. For these reasons, many methods in molecular biology and recombinant DNA technology have been developed around bacteria, and these organisms often serve as model systems for understanding cellular functions and developmental processes in more complex organisms. Much of what we know about the basic molecular mechanisms in cells, such as translation and replication, has originated with studies in bacteria. This is because such central cellular functions have remained largely unchanged throughout evolution. Ribosomes have a similar structure in all organisms, and many of the translation factors are highly conserved. The DNA replication apparatus of all organisms contains features in common such as sliding clamps and editing functions, which were first described in bacteria and their phages. Chaperones that help other proteins fold and topoisomerases that change the topology of DNA were first discovered in bacteria and phages. Studies of repair of DNA damage and mutagenesis in bacteria have also led the way to an understanding of such pathways in eukaryotes. Excision repair systems, mutagenic polymerases, and mismatch repair systems are similar in all organisms and have recently been implicated in some types of human cancers.

Also, recent evidence indicates that the cell biology of bacteria might be much more complex and more like that of eukaryotes than previously believed. For a long time it has been possible to observe the seemingly purposeful movement of constituents on the cytoskeleton within eukaryotic cells. However, bacterial cells, being much smaller, were thought to be merely “bags of enzymes” and to rely on mere diffusion to move their cellular constituents around. Now new technologies make it possible to observe movement within bacterial cells, revealing, for example, that some proteins

involved in cell division and partitioning oscillate from one end of the cell to the other during the cell cycle (see chapter 1). Bacteria even have proteins related to the proteins of the cytoskeleton, including a cell division protein called FtsZ, which is similar structurally to the tubulins that make up microtubules, and a protein called MreB, which helps give bacterial cells their structure and forms filaments like actin (see Jones et al., and van den Ent et al., Suggested Reading). It has been speculated that we might be entering another stage in biology similar to the early days of molecular genetics, when studies with bacteria led the way to the discovery of new principles of cell biology that are common to all organisms.

However, bacteria are not just important as laboratory tools to understand higher organisms; they are important and interesting in their own right. For instance, they play an essential role in the ecology of the Earth. They are the only organisms that can “fix” atmospheric nitrogen, that is, convert N_2 to ammonia, which can be used to make nitrogen-containing cellular constituents such as proteins and nucleic acids. Without bacteria, the natural nitrogen cycle would be broken. Bacteria are also central to the carbon cycle of the Earth because of their ability to degrade recalcitrant natural polymers such as cellulose and lignin. Bacteria and some types of fungi thus prevent the Earth from being buried in plant debris and other carbon-containing material. Toxic compounds including petroleum, many of the chlorinated hydrocarbons, and other products of the chemical industry can also be degraded by bacteria. For this reason, these organisms are essential in water purification and toxic waste cleanup. Moreover, bacteria produce most of the naturally occurring so-called greenhouse gases, such as methane and carbon dioxide, which are in turn degraded by other types of bacteria. This cycle helps maintain climate equilibrium. Bacteria have even had a profound effect on the geology of the Earth, being responsible for some of the major iron ore and other types of deposits in the Earth’s crust.

Another unusual feature of bacteria is their ability to live in extremely inhospitable environments, many of which are devoid of life except for bacteria. These organisms are the only ones living in the Dead Sea, where the water’s salt concentration is very high. Some types of bacteria live in hot springs at temperatures close to the boiling point of water, and others survive in atmospheres devoid of oxygen, such as eutrophic lakes and swamps.

Bacteria that live in inhospitable environments sometimes enable other organisms to survive in those environments through symbiotic relationships. For example, symbiotic bacteria make life possible for tubular worms next to hydrothermal vents on the ocean floor, where the atmosphere is hydrogen sulfide rather than oxygen. In this symbiosis, the bacteria fix carbon dioxide by using the reducing power of the hydrogen sulfide given off by the hydrothermal vents, thereby furnishing food in the

form of high-energy carbon compounds for the worms. Symbiotic cyanobacteria allow fungi to live in the Arctic tundra in the form of lichens. The bacterial partners in the lichens fix atmospheric nitrogen and make carbon-containing molecules through photosynthesis to allow their fungal partners to grow on the tundra in the absence of nutrient-containing soil. Symbiotic nitrogen-fixing *Rhizobium* and *Azorhizobium* spp. in the nodules on the roots of legumes and some other types of higher plants allow plants to grow in nitrogen-deficient soils. Other types of symbiotic bacteria digest cellulose to allow cows and other ruminant animals to live on a diet of grass. Chemiluminescent bacteria even generate light for squid and other marine animals, allowing individuals to find each other in the darkness of the deep ocean.

Bacteria are also worth studying because of their role in disease. They cause many human, plant, and animal diseases, and new ones are continuously appearing. Knowledge gained from the molecular genetics of bacteria will help in the development of new ways to treat or otherwise control these diseases.

Bacteria and their phages (i.e., viruses that infect bacteria) are also the source of many useful substances such as many of the enzymes used in biotechnology and other industries. Moreover, bacteria make antibiotics and chemicals such as benzene and citric acid.

In spite of substantial progress, we have only begun to understand the bacterial world around us. Bacteria are the most physiologically diverse organisms on Earth, and the importance of bacteria to life on Earth and the potential uses to which bacteria can be put can only be guessed at. Thousands of different types of bacteria are known, and new insights into their cellular mechanisms and their applications constantly emerge from research with bacteria. Moreover, it is estimated that less than 1% of the types of bacteria living in the soil and other environments have ever been isolated. Who knows what interesting and useful functions the undiscovered bacteria might have. Clearly, studies with bacteria will continue to be essential to our future efforts to understand, control, and benefit from the biological world around us, and bacterial molecular genetics will be an essential tool in these efforts. But before discussing this field, we must first briefly discuss the evolutionary relationship of the bacteria to other organisms.

The Biological Universe

The Eubacteria

According to a present view, all organisms on Earth belong to three major divisions: the eubacteria, the archaea (formerly archaebacteria), and the eukaryotes (Figure 1). Most of the familiar bacteria such as *Escherichia coli*, *Streptococcus pneumoniae*, and *Staphylococcus aureus* are eubacteria. These organisms can differ greatly in
