CONTENTS

VOLUME II

Chapter 5 New Concepts

"Equilibria and Stability of an Electron Beam Confined in a Torus." <i>A. Mondelli and N. Rostoker</i> (Maxwell Laboratories)	9
"Injection, Compression and Confinement of Electrons in a Magnetic Mirror." <i>A. Fisher</i> (University of California)	52
"An Electron Accelerator for Tunneling Through Hard Rock." <i>Robert T. Avery and Denis Keefe</i> (Lawrence Berkeley Laboratory)	61
"Intense Synchrotron Radiation from a Magnetically Compressed Relativistic Electron Layer." <i>J. W. Shearer, D. A. Nowak, E. Garelis, and W. C. Condit</i> (Lawrence Livermore Laboratory) . .	78
"The Plasma Focus as a Pulsed Power Source." <i>H. Sahlin, G. McFarland, R. Barlett</i> (Lawrence Livermore Laboratory) <i>R. Gullickson</i> (Air Force Ofc. of Scientific Research)	96
"Present Status of the Ion Ring Compressor Approach to Fusion." <i>H. H. Fleischmann</i> (Cornell University)	129
"TREK - Device for Obtaining Intense Relativistic Rings on the Basis of Mirror Capture." <i>V. P. Grigoryev, A. N. Didenko, Yu. P. Usov, G. P. Fomenko, E. G. Furman, V. V. Tsygankov, V. L. Chakhlov, Yu. G. Yushkov</i> (Institute for Nuclear Physics)	152

Chapter 6 Lasers

"Electron-Beam Excitation of Gas Lasers." <i>J. B. Gerardo, J. J. Ramirez, R. A. Gerber, E. L. Patterson, and K. R. Prestwich</i> (Sandia Laboratories)	169
--	-----

"Studies of the Coaxial Diode Xenon VUV Laser." E. G. Arthurs, D. J. Bradley, C. B. Edwards, S. Domanski, D. R. Hull, C. C. Ling, and M. H. R. Hutchinson (Imperial College)	193
"Future Requirements for High Voltage Electron Beam Accelerators for Excitation of Large Aspect Ratio Lasers." John L. Harrison (Maxwell Laboratories)	211
"Electron Beam Energy Deposition and VUV Efficiency Measurements in Rare Gases." C. E. Turner, Jr., P. W. Hoff and J. Taska (Lawrence Livermore Laboratory)	224
"The Physics of Relativistic Electron Beams in Rectangular and Cylindrical Geometries." L. G. Schlitt and L. P. Bradley (Lawrence Livermore Laboratory)	239
"Repetitively Pulsed Electron Beam Generator." G. K. Loda and D. A. Meskan (Systems, Science and Software)	252
"Cold Cathode Electron Guns in the LASL High Power Short-Pulse CO ₂ Laser Program." S. Singer, J. S. Ladish, and M. J. Nutter (Los Alamos Scientific Laboratory)	274

Chapter 7

Ion Acceleration and Microwave

"Collective Particle Acceleration." A. A. Kolomensky (Lebedev Physical Institute)	295
"Ionization Front Accelerator." C. L. Olson (Sandia Laboratories)	312
"Resistive Growth of the Relativistic Cyclotron Wave." M. L. Sloan (Austin Research Associates)	334
"Investigation of Ion Acceleration in Vacuum Using a Linear Electron Beam." C. N. Boyer, H. Kim and G. T. Zorn (University of Maryland)	347

"Scaling Laws for Linear Collective Ion Acceleration in the Neutral Gas Geometry." Robert B. Miller and David C. Straw (Air Force Weapons Laboratory)	368
"Electron Ring Accelerator and Collective Instabilities." U. Schumacher, M. Ulrich, W. Dommaschk, I. Hofmann, P. Merkel (Max-Planck-Institut für Plasmaphysik)	385
"Cyclotron Resonance Phenomena in Microwave and Submillimeter Radiation from an Intense Relativistic Electron Beam." V. L. Granatstein, R. K. Parker and P. Sprangle (Naval Research Laboratory)	401
"Experimental Study of Microwave Radiation in 10 CM Band of Intense Relativistic Electron Beams." A. N. Didenko, A. G. Gerlitsin, V. I. Zelentsov, G. P. Fomenko, Yu. G. Shtein, Yu. G. Yushkov (Institute for Nuclear Physics)	424

Chapter 8 Plasma Heating

"Interaction Between an Injected REB and a Tokamak Plasma." Masaru Masuzaki, Akihiro Mohri, Tetsuya Tsuzuki and Kazunari Ikuta (Nagoya University)	435
"Results from the Triton Electron Beam-Plasma Interaction Experiment." D. A. Hammer, K. A. Gerber and W. F. Dove (Naval Research Laboratory)	455
"Electron Beam Heating of Linear Fusion Devices." J. Benford, T. S. T. Young, B. Ecker, D. Dakin, I. Smith, S. Putnam and V. Bailey (Physics International Company)	476
"Plasma Heating by Relativistic Electron Beams: Correlations Between Experiment and Theory." Lester E. Thode and Brendan B. Godfrey (Los Alamos Scientific Laboratory)	509
"Self-Consistent Microwave Plasma Heating Rates." Donald L. Ensley and Richard H. White (Lawrence Livermore Laboratory)	534
LIST OF ATTENDEES	557

CHAPTER 5

NEW CONCEPTS

EQUILIBRIA AND STABILITY OF AN ELECTRON BEAM
CONFINED IN A TORUS*

A. Mondelli and N. Rostoker

Maxwell Laboratories, Inc., San Diego, California 92123

Abstract

Relativistic, cylindrical, rigid-rotor equilibria for electrons are developed in the beam frame, and the corresponding laboratory frame equilibria are obtained by Lorentz transformation. Limitations of the two-mass approximation are thus illuminated. A toroidal equilibrium is developed that is based on the two-mass approximation and expansion in terms of the ratio of minor to major radius. The toroidal equilibrium is shown to have no unstable kink-modes or no Kruskal-Shafranov current limit as in a Tokamak. Small variations in the toroidal magnetic field around the torus result in trapped electrons if they are injected with sufficient transverse energy. The presence of both trapped and untrapped electrons leads to two-stream instabilities. Some comparisons are made with HIPAC experiments and the recent torus experiments at MLI.

* Supported by the Defense Nuclear Agency

Introduction

In recent years experiments at the University of Maryland^{1,2} and at AVCO Corporation^{3,4} have demonstrated that non-neutral electron clouds can be confined for periods of 5 to 10 milliseconds in either open-end or toroidal magnetic traps. This type of device was studied at AVCO⁵ as a possible source of highly-stripped heavy ions. Rostoker⁶ has suggested that by accelerating the electron cloud to relativistic energies, enormous energy densities (up to 100 Joules per cm³) can be stored in the electrostatic and self-magnetic fields of the electron beam. Such an energy storage device could be utilized in a variety of applications. A discussion of its application to controlled thermonuclear fusion has been presented elsewhere.⁷

A central question in the discussion of this concept concerns the existence of stable, self-consistent equilibria for non-neutral, relativistic electron beams. Equilibrium and stability calculations for non-neutral electron plasma have been reported by Krall and Davidson^{8,9} and by Daugherty and Levy¹⁰ in the non-relativistic regime. Rostoker and Hieronymus (R-H)^{11,12} have considered relativistic equilibria and their stability in the framework of the "two-mass" approximation in both cylindrical and large aspect ratio toroidal geometries.

In this paper the equilibria and stability of non-neutral relativistic electron beams will be considered. A fully-relativistic equilibrium calculation for cylindrical geometry is presented and compared with the R-H model, which assumed non-relativistic perpendicular motion. The stored energy in the beam fields

is found to be higher than the predictions of the two-mass approximation when the perpendicular kinetic energy of the electrons is made relativistic. A generalization of the cylindrical two-mass equilibria into a large aspect ratio toroidal geometry is accomplished by expansion in the inverse aspect ratio. The linear stability of the electron beam is improved over that for neutral plasma because of the absence of ions, which precludes the possibility of instabilities driven by charge separation. In particular, the linear stability of the kink mode and the absence of a Kruskal-Shafranov limit are obtained. Finally, the consequences of electron trapping due to small variations in the toroidal magnetic field will be discussed.

RELATIVISTIC RIGID-ROTOR EQUILIBRIA IN CYLINDRICAL GEOMETRY

The basic features of relativistic non-neutral equilibria have been outlined by Rostoker et al.^{6,7} Consider the configuration shown in Fig. 1, where a non-neutral electron beam of uniform density, n_0 , and radius, a , propagates along an external guide field, B_z , with velocity, V_0 , and is enclosed by a concentric conducting shell of radius b . The radial force, $-e(E_r - \beta_0 B_\theta)$, when combined with the guide field, leads to a rigid rotation of the beam, $v_\theta = \omega r$, where in this simple model $\omega = \omega_p^2 / 2\gamma_0^2 \Omega_0$. Here $\beta_0 = V_0/c$, $\gamma_0 = (1 - \beta_0^2)^{-1/2}$, $\omega_p^2 = 4\pi n_0 e^2 / \gamma_0 m$, and $\Omega_0 = eB_0 / \gamma_0 mc$. The beam rotation produces a diamagnetic macroscopic current density, J_θ , thereby reducing B_z within the beam and allowing equilibrium pressure balance to be achieved.

The form of the total kinetic energy of the electron, $(\gamma - 1)mc^2$, where

$$\gamma = \frac{1}{\sqrt{1 - \beta_0^2 - (v_\theta/c)^2}} = \frac{\gamma_0}{\sqrt{1 - (\gamma_0 v_\theta/c)^2}}, \quad (1)$$

shows immediately that $\gamma_0 v_\theta < c$ is required. That is, in the beam frame (denoted by prime), $v'_\theta = \gamma_0 v_\theta < c$. In the limit, $\gamma_0 v_\theta \ll c$, an expansion of γ in powers of $\gamma_0 v_\theta / c$ yields the two-mass approximation.

From the requirement that the electron orbits be stable, it is evident that there is no equilibrium when $B_0 = 0$. In fact, in the simple model depicted in Fig. 1, the guide field must be large enough to satisfy

$$q^2 \equiv \frac{\omega_p^2}{2\gamma_o^2 \Omega_o^2} \leq \frac{1}{4} .$$

Using the two-mass approximation equations of motion and performing an expansion to second order in the assumed small parameter, q , R-H^{11,12} obtain the single-particle equations of motion

$$\gamma_o m \left[\frac{dv_r}{dt} - \frac{v_\theta^2}{r} \right] = -e \left[E_r + \frac{1}{c} (v_\theta B_z - v_z B_\theta) \right] \quad (2)$$

$$\gamma_o m \left[\frac{dv_\theta}{dt} + \frac{v_r v_\theta}{r} \right] = \frac{e}{c} v_r B_z$$

$$\gamma_o^3 m \frac{dv_z}{dt} = -\frac{e}{c} v_r B_\theta = \frac{e}{c} \frac{dA_z}{dt} \simeq 0$$

The single-particle constants of motion which follow from the equations are

$$H_1 = \frac{1}{2} \gamma_o m (v_r^2 + v_\theta^2) - e(\Phi - \beta_o A_z) \quad (3)$$

$$P_\theta = \gamma_o m r v_\theta - \frac{e}{c} r A_\theta$$

$$v_z = V_o ,$$

to order q^2 , where all quantities are assumed to depend only on the radial coordinate.

The equilibrium distribution function can be any function of the constants of motion. In particular, R-H examined the function

$$F(\underline{r}, \underline{v}) = \frac{\gamma_o^{mn} n_o}{2\pi} \delta[H_{\perp} - \omega p_{\theta} - e_o] \delta[v_z - v_o], \quad (4)$$

corresponding to a uniform density, finite radius beam, which rigidly rotates at the frequency

$$\omega = \frac{\Omega_o}{2 \left[1 + \frac{1}{4} \left(\frac{\omega_p a}{c} \right)^2 \right]} \left\{ 1 - \sqrt{1 - \frac{2}{\gamma_o} \left(\frac{\omega_p}{\Omega_o} \right)^2 \left[1 + \frac{1}{4} \left(\frac{\omega_p a}{c} \right)^2 \right] \left[1 + \frac{2\gamma_o^2 \langle v_{\perp}^2 \rangle}{\omega_p^2 a^2} \right]} \right\}$$

$$\approx \frac{1}{2\gamma_o^2} \frac{\omega_p^2}{\Omega_o} \left[1 + \frac{2\gamma_o^2 \langle v_{\perp}^2 \rangle}{\omega_p^2 a^2} \right], \quad (5)$$

where $\langle v_{\perp}^2 \rangle \equiv [\langle v_r^2 \rangle + \langle v_{\theta}^2 \rangle]_{r=0}$ is a measure of transverse temperature, and $\langle \rangle$ denotes the velocity-space average of the enclosed quantity weighted by $F(\underline{r}, \underline{v})$.

This self-consistent equilibrium reproduces the simple model described earlier with the inclusion of $\langle v_{\perp}^2 \rangle$. The conditions for this equilibrium to exist are $\langle v_{\perp}^2 \rangle > 0$ and

$$q^2 \equiv \frac{1}{2\gamma_o^2} \left(\frac{\omega_p}{\Omega_o} \right)^2 \leq \left\{ 4 \left[1 + \frac{1}{4} \left(\frac{\omega_p a}{c} \right)^2 \right] \left[1 + \frac{2\gamma_o^2 \langle v_{\perp}^2 \rangle}{\omega_p^2 a^2} \right] \right\}^{-1} \quad (6)$$

which we plot in Fig. 2. From the figure we see that $q^2 \ll 1$ is required when $\omega_p a/c \gg 1$, which corresponds to the limit of high v/γ_o .

The existence of a small parameter, q , in non-relativistic equilibria was noted by Daugherty and Levy.¹⁰ For fixed values of density and magnetic field the relativistic value of q is

$1/\gamma_0$ - fold smaller than its non-relativistic value. The advantage of using a relativistic electron beam instead of a non-relativistic electron cloud is that equilibria can sustain γ_0 - times higher electron density at a given value of B_0 . The field energy is therefore γ_0^2 - fold higher in the relativistic system. This improvement is due to the reduction in the self-field stress, $(E_r^2 - B_\theta^2)/8\pi$, when the system is relativistic, since $B_\theta = \beta_0 E_r$. While this stress is very small for a relativistic system, the energy density, $(E_r^2 + B_\theta^2)/8\pi$, associated with the beam self-fields can be quite high, limited only by ion field emission from the conducting outer shell. Self-consistent equilibria in which the beam-associated field energy density exceeds both the guide field energy density and the particle kinetic energy density are therefore possible.

To verify this model and to obtain the effects associated with high perpendicular particle energy, $\gamma_0 v_\theta/c \lesssim 1$, a fully-relativistic formulation of the equilibrium is required. In terms of the fully-relativistic single-particle constants of motion in the beam frame (prime),

$$H' = mc^2 \sqrt{1 + (p'/mc)^2} - e\Phi' \quad (7)$$

$$p'_\theta = r'(p'_\theta - \frac{e}{c} A'_\theta)$$

$$p'_z = p'_z,$$

where $p'_z = \gamma' m v'_z$ and $p'_\theta = \gamma' m v'_\theta = (p'_y x' - p'_x y')/r' = p'_\perp \sin(\varphi - \theta)$, consider an equilibrium distribution function of the form

$$F(\underline{r}', \underline{p}') = K' \delta [H' - \omega' P'_\theta - \varepsilon'_0] \delta(\underline{p}'_z) . \quad (8)$$

Introducing the variable $y = \sqrt{1 + (\underline{p}'_\perp/mc)^2}$, the density and macroscopic velocity may be evaluated as follows

$$\begin{aligned} n'(\underline{r}') &= \int F(\underline{r}', \underline{p}') d\underline{p}' \\ &= K'm \int_1^\infty y dy \int_0^{2\pi} d\varphi \delta \left[y - \frac{\omega' r'}{c} \sqrt{y^2 - 1} \sin(\varphi - \theta) - g'(\underline{r}') \right] \end{aligned}$$

$$n'(\underline{r}') \langle v'_\theta \rangle = K'm \int_1^\infty y dy \int_0^{2\pi} d\varphi \frac{c\sqrt{y^2 - 1}}{y} \sin(\varphi - \theta)$$

$$\delta \left[y - \frac{\omega' r'}{c} \sqrt{y^2 - 1} \sin(\varphi - \theta) - g'(\underline{r}') \right] ,$$

where

$$g'(\underline{r}') = \frac{1}{mc^2} \left[\varepsilon'_0 - \frac{e\omega' r'}{c} A'_\theta + e\phi' \right] .$$

To carry out the indicated integrations, the δ -function may be expressed as

$$\frac{1}{\frac{\omega' r'}{c} \sqrt{y^2 - 1}} \frac{2}{|\cos \varphi_0|} \delta(\varphi - \varphi_0) ,$$

where

$$\cos \varphi_0 = \frac{\left\{ \left(\frac{\omega' r'}{c} \right)^2 (y^2 - 1) - [y - g'(\underline{r}')]^2 \right\}^{\frac{1}{2}}}{\left(\frac{\omega' r'}{c} \right)^2 \sqrt{y^2 - 1}}$$
