# PREFACE

There is nothing new under the sun and so it would be foolhardy to suggest that *Molecular Biology Labfax* is an entirely new departure in scientific publishing. It is, however, different from the existing cloning manuals in that it is designed as a companion rather than a guide for molecular biology research. *Molecular Biology Labfax* does not contain procedures or methodology but instead is a detailed compendium of the essential information — on genotypes, reagents, enzymes, reaction conditions, cloning vectors and suchlike — that is needed to plan and carry out molecular biology research. Some of this information is already available in cloning manuals, catalogs and possibly on pieces of paper kept somewhere safe, but tracking down exactly what you need to know takes time and can be a frustrating experience. With molecular biology becoming an increasingly sophisticated science, an acute need has arisen for a databook to complement the traditional cloning manuals. *Molecular Biology Labfax* is intended to meet this need.

To be useful, the coverage of *Molecular Biology Labfax* has to be right. The scope of the book is of necessity a compromise between a desire to include everything and a need to keep within a reasonable size limit. The reader will expect to find extensive details of *Escherichia coli* genotypes and genetic markers, restriction enzymes, DNA and RNA modifying enzymes, chemicals and reagents, cloning vectors, restriction fragment patterns and suchlike. These topics are covered in as comprehensive a way as possible, so for instance in Chapter 4 all the known restriction enzymes are described along with reaction conditions for all the commercially available ones. A few items that might be expected are not included on the basis that they are of specialist interest, an example being cloning vectors for eukaryotes. Topics such as these will be covered by future editions in the Labfax series. Although experimental protocols are not given, certain key information is provided for subjects such as the growth of *E. coli* strains, use of radiochemicals, electrophoresis of nucleic acids, and hybridization analysis. These topics are of widespread importance in molecular biology procedures and so warrant sections of their own. Readers using other standard techniques will find their needs met by the data presented throughout the book. For instance, the DNA sequencer will find data on dideoxynucleotides and Maxam-Gilbert reagents (Chapter 2), radionucleotides and detection methods (Chapter 3), enzymes for chain termination sequencing (Chapter 5), M13 cloning vectors (Chapter 6), and electrophoresis systems (Chapter 8), as well as details of the genetic code and codon usages for interpretation of sequence information (Chapter 7).

A second essential requirement is accuracy. Wherever possible I have double-checked items that I have had doubts about, going back to the original publications if necessary. In a few cases the literature contains annoying contradictions that I have been unable to resolve, with *E. coli* genotypes providing some of the biggest headaches. The relevant entries carry a footnote or other warning to alert the reader and I welcome enlightenment if anyone knows any of the answers.

Without the help of a number of people *Molecular Biology Labfax* would never have been completed. I am very grateful to Rich Roberts, Toshimichi Ikemura and Michael McClelland for their contributions, as well as GIBCO-BRL, Pharmacia, Promega, USB, Clontech, Stratagene

and FMC for providing artwork for the cloning vectors and electrophoresis sections. I would like to give a general thank-you to the various colleagues and friends who helped me out with points here and there. Half-way through the enterprise it became clear that you need to be slightly unbalanced to compile a databook: I became even more worried on the occasions when I thought I was actually enjoying the experience. Because of this I must thank my wife, Keri, who made sure I survived to tell the tale.

T.A. Brown

# **SAFETY NOTE**

Safety is a critical aspect of laboratory work and all molecular biologists should be aware of the precautions needed to ensure personal safety and the safety of colleagues. National and local safety precautions must be followed at all times. All reputable suppliers of laboratory chemicals provide risk and safety information with those products that present a potential hazard, but several risk and safety classification schemes exist. This book cites risk and safety data for products where appropriate: full details of the classification schemes used, together with information on protection from microbiological and radiochemical hazards, are given in Chapter 11.

# CHAPTER 1

## BACTERIA AND BACTERIOPHAGES

### 1. *E. COLI* STRAINS USED IN RECOMBINANT DNA EXPERIMENTS

The *E. coli* strains routinely used in recombinant DNA experiments are listed with their genotypes in *Table 1*. The genotypes are described in accordance with the standard nomenclature as defined below.

#### 1.1. Individual genes

- (i) Each mutant locus is described by a three-letter abbreviation (e.g. *ara* = arabinose utilization). The abbreviations are defined in *Table 2*.
- (ii) The capital letter following the locus refers to the individual gene that is mutated (e.g. *araD* = L-ribulosephosphate 4-epimerase). The genes are also described in *Table 2*.
- (iii) Numbers following the gene designation refer to the specific allele involved (e.g. *araD139*).
- (iv) A superscript '-' is generally not used, since, by convention, only mutated genes are listed in the genotype. A superscript '+' may be used to emphasize a locus or gene that is wild-type (e.g. *lac*<sup>+</sup> = no mutations in the genes involved in lactose utilization).
- (v) A superscript 'q' indicates a constitutive mutation (e.g. *lacI*<sup>q</sup> = constitutive mutant for the *lac* repressor).
- (vi) An amber mutation is denoted by 'am' following the gene designation (e.g. *malBam*).
- (vii) If an antibiotic response is listed in the genotype then a superscript 'r' or 's' is used to denote resistance or sensitivity respectively (e.g. *kan*<sup>r</sup> = kanamycin resistant).

#### 1.2. Deletions

Deletions are denoted by 'Δ' with the deleted gene or genes listed in brackets, possibly followed by an allele designation outside of the brackets [e.g. Δ(*gal-uvrB*)40 = deletion of the region from *gal* to *uvrB*].

#### 1.3. Fusions

- (i) A fusion is denoted in the same way as a deletion, except that the symbol 'Φ' is used.
- (ii) A prime (') is used to designate that the fused gene is incomplete (e.g. '*lacZ*' indicates that the *lacZ* gene involved in the fusion is deleted in the 5' region; *lacZ*' indicates a deletion in the 3' region).
- (iii) A superscript '+' (e.g. *lacZ*<sup>+</sup>) denotes that the fusion involves an operon rather than a single gene.

#### 1.4. Insertions

- (i) An insertion is denoted by '::', preceded by the position of the insertion and followed by the inserted DNA (e.g. *trpC22::Tn10* = insertion of *Tn10* into the *trpC* gene, allele 22).
- (ii) If the insertion does not occur within a known gene then the map position is denoted by a three-letter code. The first letter is always *z*, followed by *a-g* to indicate a 10 min interval, and *a-i* to indicate a 1 min interval (e.g. *zgi* = 79 min).

## 1.5. Phages and plasmids

A plasmid or lysogenic phage carried by the bacterium is listed at the end of the genotype in brackets [e.g. (pMC9) = carries plasmid pMC9].

## 1.6. Fertility status

- (i) Strains are assumed to be F<sup>-</sup> unless the status is given.
- (ii) F<sup>+</sup> and Hfr strains are denoted by the relevant symbol at the start of the genotype.
- (iii) When the strain is listed as F', the genes carried on the episome are listed in square brackets. The F' status is usually placed at the end of the genotype.

The full restriction and modification status of individual strains is not given in Table 1. The genotypes are correct for *hsdR*, *hsdS* and *hsdM*, but *mcrA*, *mcrB* and *mrr* are not included. This is because for many strains the *mcrA*, *mcrB* and *mrr* genotypes have not yet been determined. Full descriptions of the restriction and modification status, as far as is known, of important strains are given in Table 3. Table 4 classifies strains according to their specific application(s) in recombinant DNA experiments.
