## FOREWORD

The detailed, descriptive information in this book is based on the U.S. patent literature since 1966 relating to the manufacture and use of water-soluble polymers.

The patents included in the chapter on starch, modified starch and derivatives are very recent, all issued since 1971, because there is such a large mass of material in this important and very active field.

For a detailed review of the earlier work in this particular field, the reader is referred to "Starches and Corn Syrups" by Dr. A. Lachmann, Noyes Data Corporation 1970.

This book serves a double purpose in that it supplies detailed technical information and can be used as a guide to the U.S. patent literature in this field. By indicating all the information that is significant, and eliminating legalistic phraseology, this book presents an advanced commercially oriented review of water-soluble polymers and the associated technology.

The U.S. patent literature is the largest and most comprehensive collection of technical information in the world. There is more practical, commercial, timely process information assembled here than is available from any other source. The technical information obtained from a patent is extremely reliable and comprehensive; sufficient information must be included to avoid rejection for "insufficient disclosure".

The patent literature covers a substantial amount of information not available in the journal literature. The patent literature is a prime source of basic commercially utilizable information. This information is overlooked by those who rely primarily on the periodical journal literature. It is realized that there is a lag between a patent application on a new process development and the granting of a patent, but it is felt that this may roughly parallel or even anticipate the lag in putting that development into commercial practice.

Many of these patents are being utilized commercially. Whether used or not, they offer opportunities for technological transfer. Also, a major purpose of this book is to describe the number of technical possibilities available, which may open up profitable areas of research and development.

These publications are bound in paper in order to close the time gap between "manuscript" and "completed book". Industrial technology is progressing so rapidly that hard cover books do not always reflect the latest developments in a particular field, due to the longer time required to produce a hard cover book.

The Table of Contents is organized in such a way as to serve as a subject index. Other indexes by company, inventor, and patent number help in providing easily obtainable information.

## CONTENTS AND SUBJECT INDEX

INTRODUCTION	1
1. MARKET SURVEY	2
Starch	2
Grain Crop Price Structure	2
Corn Starch and Corn Syrup Price Structure	3
Major U.S. Producers of Corn Starch	3
Natural Gums	4
Import Statistics	4
Polyvinyl Alcohol (PVA)	6
Applications	6
Producers	6
Price	6
Growth and Forecasts	7
Cellulose Ethers	7
Basic Information	7
Production and Sales of Cellulose Ethers	8
Sodium Carboxymethylcellulose (CMC)	8
Applications	8
U.S. Producers	8
Price	9
Growth and Forecasts	9
Acrylic Acid and Methacrylic Acid Polymers	10
Applications of Polyacrylic Acids and Their Salts	10
Producers	10
Polyacrylic Acid Salts	10
Overall Forecast	11
2. ACRYLAMIDE POLYMERS	13
Processing	13
Ultraviolet Hardening of Photosensitized Polyacrylamide	13
Applications	15
Aqueous Slurried Explosive of Improved Pourability	15
Lubricant-Coolant	18
Method of Reducing Friction Losses in the Flow of Aqueous Fluids	20
Aqueous Starch-Pigment Paper Coating Compositions Containing Polyacrylamide-Glyoxal Latent Insolubilizer	22
Friction Reducing Compositions for Oil-Based Fracturing Fluids	24
Chromatographic Adsorbents	29
Separation of Solids from Liquids	31
Extruded Catalysts and Catalyst Supports Containing Polyacrylamide	34
3. ACRYLIC ACID AND METHACRYLIC ACID POLYMERS	38
Processing	38
Polymerization with a Redox and Azoisobutyronitrile Catalyst	38
Ethylene-Acrylic Acid or Ethylene-Acrylamide-Acrylic Acid Polymers	39
Stabilized Suspension Polymerization	41
Solvent Systems for Copolymers of Ethylene and Acrylic Acid	43
Ethylene-Aminoalkyl Ester Copolymers	44
Improved Reppe Process Preparation	45
Applications	48
Preparation of Spray-On Bandage	48
Foundry Sand Compositions	50
Siloxane-Acrylate Copolymers and Emulsions	52
Flocculating Agent	53
Wallpaper Coating	56
Water Treatment	58
Hot-Melt Adhesives	60

4. CELLULOSE ETHERS AND RELATED PRODUCTS	63
Sulfonamide Modification	63
Quaternary Nitrogen-Containing Cellulose Ethers	66
Partial Cellulose Ethers with Strong Anion Exchange Properties	71
Insolubilizing Water-Soluble Polymers by Curing	73
Dissolution of Cellulose Ethers	76
Fiber-Free Alkyl and Hydroxyalkyl Cellulose Ethers	77
Surface-Sulfonated Cellulose Ethers Having Improved Water-Dispersibility	78
Producing Absorbent Cellulose Particles by Shear Precipitation	80
5. SODIUM CARBOXYMETHYLCELLULOSE - CMC	84
Processing	84
High Viscosity CMC by Addition of Trichloroacetic Acid or Its Salts	84
Introducing Carboxyalkyl and/or Carbamoylalkyl Groups into Cellulosic Textile Materials	86
Carboxymethylhemicelluloses	88
Close Control of CMC Viscosity Using an Oxygen Process	89
Apparatus for Increasing the Productivity of CMC Manufacture	90
Increasing the Thickening Power of Water-Soluble Alkali Metal Salts of Carboxymethylcellulose	93
A Low-Cost Process for Manufacturing CMC	94
Multicomponent Water-Miscible Diluent System	96
Smooth, Low-Thixotropic CMC Solutions	99
Acetone Slurry Process with High Reaction Efficiency	102
Manufacturing Highly Uniformly Substituted CMC	104
Applications	107
Phosphate-Free Heavy Duty Detergent Formulations	107
Improving the Use of CMC for Oil Well Drilling Muds	108
6. HYDROXYETHYLCELLULOSE - HEC	111
Hydroxyalkylating Cellulose Derivatives	111
Low Sulfate Ash HEC	112
Forming Highly Clear Filterable HEC Solutions	113
Improved Oxidative Aging of HEC	115
Dispersants Used in the Preparation of HEC	117
7. HYDROXYPROPYLCELLULOSE - HPC	119
Improved Hydroxypropylcellulose	119
Use of a Water Immiscible Dispersant or Water Miscible-Water Immiscible Mixed Dispersant for HPC Preparations	122
HPC Compounds with M.S. of 2 to 10	124
Propylene Oxide as a Diluent and Etherification Agent	128
8. METHYL CELLULOSE - MC	129
Processing	129
Continuous Process for Preparing Methyl Cellulose and Its Derivatives	129
Applications	132
Methyl Cellulose as a Starch Substitute	132
9. OTHER CELLULOSE DERIVATIVES	136
Hydroxyethyl Hydroxypropyl Cellulose - HEHPC	136
High Thermoplasticity	136
Ethyl Cellulose - EC	138
Reducing the Viscosity of Ethyl Cellulose	138
Epoxy Derivatives	140
Soluble Epoxy Derivatives of Cellulose	140
10. ETHYLENE OXIDE POLYMERS AND RELATED PRODUCTS	143
Processing	143
Producing High Molecular Weight Polymers of Alkylene Oxides	143
Oxidation of Alkenes to Alkene Oxides	149
Oxidation of Alkanes and Alkenes to Nitriles	150
Applications	151
Sulfuric Acid Esters of Butynediol-Polyalkylene Oxide Condensates as Antifoggant in Silver Halide Emulsions	151
Quaternary Adducts of Polyepihalohydrin	153
Stabilized Nonionic Surfactants in Solid Formulations Containing Active Chlorine Compounds	155
Fiber Lubricating Composition	156
Photographic Emulsion Containing a Water-Soluble Alkylene Oxide Block Copolymer and a Merocyanine Dye	158
11. POLYETHYLENIMINE AND RELATED PRODUCTS	162
Processing	162
Polyethylenimine Boranes and Their Preparation	162
Water-Soluble Copolymers of Alkyleneimine and Alkylene Sulfide	163
Polyamines Stabilized with Aminocarboxylate Chelants	165
Selective Alkylation of Polyalkylene Polyamines	167
Preparation of 2-Chloroalkylisothiocyanates	170
Oligomers of Alkyl Aziridinyl Carboxylates	171
Copolymer of Ethylenimines and Lactones	173
Poly(N-Acylethylenimines) from 2-Substituted-2-Oxazolines	175
Single-Step Process for Preparing 1,1,4-Trisubstituted Piperazinium Salts	178
Cross-Linked Water-Soluble Polymer of Diglycidyl Ether and an Alkanolamine	179
Fluorinated Copolymers of Alkyleneimines	181

# Contents and Subject Index

Applications	182
Polyalkylene Polyamine Thiosulfonated Sulfur Dye Composition	182
Sizing Paper with Either Sulfone, Sulfoxide or Sulfide and a Polyalkylenimine	183
Fluoroamido-Amino Polymers for Imparting Oleophobic Yet Hydrophilic Properties to Fabrics	186
Metal Oxide or Hydroxide and Polyethylenimine	189
Leachproof Fire-Resistant Complex for Cellulosic Substrates	189
Bright Zinc Electroplating	191
Sequestering Ion Exchange Resins Which are Polyimine Reaction Products	193
12. POLYVINYL ALCOHOL - PVA	196
Processing	196
Vinyl Ester Polymerization in Alcohol and Water Solution	196
Use of Hydrazine to Inhibit Vinyl Polymerization	199
Soluble Polyvinyl Esters from High Molecular Weight Acid Chlorides	202
Melt-Formable Polyvinyl Alcohols	204
Polyvinyl Alcohol and Derivatives Cross-Linked with Titanium, Permanganate or Vanadyl Ions	207
Water-Soluble Modified Polyvinyl Alcohol Films	208
Production of Granular Polyvinyl Alcohol	210
Polymerization of Aldehydes in the Presence of Anhydrous Polar Solvents and Alkali Metal Alkoxide Catalysts	212
Process for Manufacturing PVA of a Predetermined Viscosity	214
Applications	221
Water-Soluble Copolymer and Its Use as a Pigment Retention Aid	221
Polymerization of Vinyl Chloride in the Presence of PVA and a Protective Colloid	222
Polyolefin/PVA Packaging Materials	226
Production of Paper of Polyvinyl Alcohol Synthetic Fibers	231
Producing a Coated Paper	234
Coating a Substrate with Capsules	237
Electrophotographic Reproduction Employing Bi-Charging and Negative-Charging Zinc Oxide	239
Shaped Articles with Improved Water Repellency and Abrasion Resistance	241
Process for Producing Color Television Tubes	245
Vinyl Acetate-Methyl Butenol Copolymers	247
Making Improved Films from Saponified Ethylene-Vinyl Acetate Copolymers	249
13. POLYVINYLPYRROLIDONE AND RELATED PRODUCTS	253
Processing	253
Functional Polymers from N-Vinylpyrrolidone	253
Applications	254
Method of Gelling Organic Polar Liquids	254
Polyamides with Improved Transparency Containing PVP	257
Cosmetic and Pharmaceutical Compositions	258
PVP Pigment Shock Reducer	260
Stable Solutions of Oxytetracycline	261
Coated Confectionery	263
Stabilization of Beer	264
Granulate Feed	266
Photographic Compositions	267
Stabilized Cyanmethemoglobin Reagent Containing Ferricyanide, Cyanide and PVP	269
Producing Dye-Receptive Filaments	271
Solid Stabilized Hydrogen Peroxide Compositions	272
Cement Additives Containing PVP and a Condensate of Sodium Naphthalene Sulfonate with Formaldehyde	275
14. STARCH, MODIFIED STARCH AND STARCH DERIVATIVES	278
Processing	278
Starch Levulinates	278
Desolventizing of Starch	280
Potato Starch Properties Controlled by Heating in Aqueous Suspension	282
Highly Hydroxypropylated Granular Potato Starch	284
High Maltose Conversion Products	287
Pregelatinized Starch Products	289
Producing Bacterial Isoamylase	292
Low DE Starch Conversion Products	293
Acetylation of Starch	295
Sulfite-Carbonyl Starch Complex	297
Obtaining Amylose from Cooked Starch Solutions	298
Phosphoric Acid Derivatives of Starch	301
Improved Process for Preparing Gelatinized Carboxyalkyl Starch Derivatives	304
High Amylose Starch Acetate	306
Process for the Inhibition of Granular Starch Bases	307
Starch Phosphonates	309
Applications	310
Pulpy Textured Food Systems Containing Inhibited Starches	310
Producing Beer	312
Sugar Production from Amylaceous Materials	314
Freeze-Thaw Resistant Flour and Starch Thickener Blend	317
COMPANY INDEX	319
INVENTOR INDEX	320
U.S. PATENT NUMBER INDEX	322

## INTRODUCTION

Synthetic water-soluble polymers are making increasing inroads into the more than 10,000 million pound per year worldwide water-soluble polymer market. These inroads have been made primarily in the industrialized countries of the world, especially in the United States, Japan, West Germany, the United Kingdom, France, the Netherlands and Italy. Adequate figures are not available on production in the Eastern European countries, the Soviet Union and Mainland China, but it is known that the Eastern European countries and the Soviet Union have substantial production facilities and that they are involved in further expansion of their output. Mainland China has a need for much of the required know-how.

One reason why the synthetics have been successful is that the use of traditional starch products in many industrial operations has been found to cause stream pollution, while the synthetics, with lower B.O.D. (Biological Oxygen Demand), have sharply reduced such pollution. In addition, the synthetics can be controlled more directly for end uses than the traditional starch products and the natural gums. As a result of the growth of the synthetics, starch manufacturers have improved their processing of starch and have concentrated research and development heavily upon developing modified starches and starch derivatives. The starches, modified starches and starch derivatives, in the competitive struggle for markets, have the great advantage of usually being much less expensive than the synthetics.

The vastly overwhelming portion of worldwide water-soluble polymer production consists of starch products (estimated at over 9,000 million pounds), followed in size by the natural gums, and the synthetics, polyvinyl alcohol and cellulose ethers. Smaller amounts are accounted for by the synthetics, acrylamide polymers, acrylic acid polymers, ethylene oxide polymers, polyethylenimine and polyvinylpyrrolidone.

Classifications: In the trade, water-soluble polymers are also known as "water-soluble resins," "hydrocolloids," and "gums."

Applications: Some of the main applications of water-soluble polymers are in adhesives, construction, cosmetics, detergents, explosives, food, oil-well drilling, paints, paper, pharmaceuticals and textiles. For individual countries and individual water-soluble polymers, the breakdowns often vary widely.

Rheology: One very basic characteristic of water-soluble polymers is the viscosity of solutions. There are several methods for measuring viscosity (e.g., use of the Hoesppler Viscosimeter, the Scott Viscosimeter and the Brabender Amylograph), but a particularly popular one is the determination of the shear stress of the solution against the rate of shear through the use of the Brookfield Synchro-Lectric Viscometer. The Brookfield Viscometer employs spindles which rotate in the solution at controlled speeds which can be varied. Viscosity is usually stated in units of centipoises.

The viscosity of aqueous solutions of water-soluble polymers is temperature-dependent, with the relationship exponential. Thus, a small change in temperature can result in a very large change in viscosity. Water-soluble polymer solutions are non-Newtonian (i.e., as the rate of shear increases, the shear stress does not increase in the same proportion), with few exceptions. Some non-Newtonian fluid properties are pseudoplasticity, plasticity and dilatancy. In addition, there are water-soluble polymer solutions which are thixotropic. For certain applications, it is desirable to have thixotropic solutions, for example, in special paints.

## MARKET SURVEY

### STARCH

Corn starch accounts for over one-half of the approximately 9,000 million pounds of starch produced in the world (excluding Eastern Europe, the Soviet Union and Mainland China), potato starch for about 30% and wheat, rice, tapioca and sago starches comprise most of the remainder. For the period 1960 to 1964, the U.S. Department of Agriculture has determined that, on the average, more than 5,000 million pounds of starch were produced in the United States by wet milling. About 60% of output was converted to syrup, sugar, dextrin and other products, and the remainder was shipped as starch.

The prices of starches are subject to such factors as the uncertainties of crop production (e.g., weather conditions) and governmental policies. Thus, the 1971 bumper crops of corn and wheat in the United States resulted in low grain prices in the latter part of 1971. The actual 1972 price structure, however, will depend upon the policy of the U.S. Government.

### Grain Crop Price Structure

The last period of high price support loan rates by the U.S. Government (i.e., the rates at which farmers in the U.S. federal program may obtain nonrecourse government loans) was in the 1950's. During most of that decade, corn price support loans averaged over \$1.50 per bushel compared to an average of \$1.05 per bushel in recent years. Actual market prices of corn during most of the 1950's, averaged well above prices in recent years, but below the then existing support loan rates. For example, in the immediate post-Korean War period of 1953 to 1954, seasonal average corn prices received by U.S. farmers declined to \$1.46 per bushel compared to an average support loan rate of \$1.61 per bushel. Since enactment of the 1962 feed grain program, farm price support loan rates have been lower and closer to market clearing levels, with farmers receiving additional income support through direct payments. Between 1965 and 1970, corn prices averaged \$1.17 per bushel compared to an average loan rate of \$1.05 per bushel.

During 1971, with the blight- and drought-reduced 1970 corn crop resulting in high grain prices, U.S. farm policy moved closer to a market-orientated agricultural system following removal of feed grain and wheat acreage restrictions. The Federal Reserve Bank of Chicago has pointed out that under previous farm programs, planted acreage of feed grains and wheat was restricted to the farm's feed grain base and wheat allotment. Under the 1971 programs, cooperating farmers were allowed to plant as much of any crop as they wished regardless of their base or allotment after setting aside a specified amount of cropland. Farmers responded to the relaxed government controls and high market prices in the spring of 1971 with a sharp increase in feed grain and wheat acreage. The increased acreage coupled with very favorable growing conditions resulted in a record-large grain harvest and sharply lower prices.

The 1971 experience reaffirms the chronic tendency of farmers to overproduce in the absence of effective production controls and no program has yet solved this problem. High price support loan programs have resulted in large government-owned surplus stocks and eventual disposal problems. Direct payment and lower price support programs, on the other hand, have resulted in steadily rising payments to farmers to curb production.

During the 1950's, government stocks of corn (owned and under loan) rose from a Korean War low of 300 million bushels to 1,400 million bushels. By 1959, stocks were equal to over 40% of annual production. After the enactment of the 1962 feed grain program, government-controlled surplus stocks were gradually reduced. In 1970, they equaled 13% of annual production. Stocks dipped to 8% of production, following the blight- and drought-reduced crop of 1970. As government stocks declined, however, direct outlays to farmers increased sharply. Payments to feed grain producers increased from about \$840 million in 1962 to \$1,300 million in 1970 (or 55%). The graph shown on the following page indicates the trend of U.S. Government corn stocks for the period 1955 to 1970.

## Market Survey

Source: Federal Reserve Bank of Chicago

The "Strategic Grain Reserve Bill" proposes stockpiling of feed grains and wheat and boosting government support loan rates for these commodities by 25%. A strategic stockpile of grain, while boosting support loan rates, probably would have the immediate effect of raising farm prices. As experience has shown, however, the higher prices would be short-lived unless direct government payments were increased to remove more cropland from production or government surplus stocks were allowed to build to absorb the increased production resulting from the higher prices. Either alternative would require a substantial increase in government outlays for agriculture, which comes at a time of a general U.S. federal policy of budgetary restrictions.

Corn prices in early 1972 will depend largely upon the amount of direct government purchases and the extent to which farmers take advantage of the government loan program. Direct purchases of corn have so far been small, but corn placed under loan is running more than triple the year earlier level. Almost 85% of the U.S. crop is eligible for government loans in 1972, compared with only 44% in 1971.

Corn supplies exceed expected needs by 1,400 million bushels in the 1972 marketing year, the largest excess supply in seven years. As a result, corn prices will likely average near the support loan rate of \$1.08 per bushel plus storage and handling charges. A large increase in idled acreage this year, however, could provide strength to corn prices late in 1972. The announced goal of the U.S. Department of Agriculture is to idle 38 million feed grain acres in 1972, which is double that of 1971. If achieved, this is expected to result in a 12% reduction in corn acreage from 1971 (See Federal Reserve Bank of Chicago, Agricultural Letters of January 7, 1972.)

### Corn Starch and Corn Syrup Price Structure

A sharp drop in the prices of corn starch and corn syrup took place in the fourth quarter of 1971 as a result of the enormous bumper corn crop that year. The entire price structure of the corn starch-corn syrup market became abnormally depressed and this condition has persisted into early 1972, with prices presently quoted at \$5 to \$5.15 per hundred pounds for unmodified corn starch. Prices are likely to move up until mid 1972, but as the year progresses U.S. governmental policy can be expected to make its effects more strongly felt. In October 1971, when the sharp drop in corn starch and corn syrup set in, CPC International, the world's largest private purchaser of corn, was instrumental in stabilizing prices. CPC International is also the world's largest corn refiner and manufacturer of starch, corn syrup, dextrose and corn oil.

### Major U.S. Producers of Corn Starch

- American Maize-Products Company
- Anheuser-Busch, Incorporated
- Clinton Corn Processing Company (a division of Standard Brands, Inc.)
- CPC International, Incorporated
- Hubinger Company
- National Starch and Chemical Corporation
- Penick & Ford, Ltd. (a subsidiary of R.J. Reynolds Industries)
- A.E. Staley Manufacturing Company
- Miles Laboratories, Incorporated

## Market Survey

### NATURAL GUMS

There are many types of natural gums. They are polysaccharides obtained from plants, trees and seeds. Production takes place in many parts of the world. Some well-known natural gums are listed below:

Guar Gum — Obtained from the seeds of plants grown in India, Pakistan and the United States.

It is used in ice cream, sherbets, cream cheese, oil-well drilling muds, paper and pharmaceuticals.

Gum Arabic (Gum Acacia) — An exudate from the bark of the acacia tree found in Senegal, the Sudan, Turkey and other countries. It is used in foods, beer and other beverages.

Gum Tragacanth — An exudate from the Asiatic plant *Astragalus gummifer*. It is used in dietetic foods, salad dressings, ice cream, candies and hand lotions.

Karaya Gum — Exudate of the *Sterculia* trees of India. It is used as a bulk laxative and dental adhesive, and in ice cream, paper and textiles.

Locust Bean Gum (Carob Bean Flower) — Obtained from the seed of the Mediterranean locust tree *Ceratonia siliqua*. It is used in cakes, ice cream, oil-well drilling muds, paper processing, textiles, and as an antidiarrheic.

These are only a few of the many natural gums. It is extremely difficult to determine how much natural gum is produced in the world because the occurrence of the plants, trees and seeds is so widespread and production and use of the gums often remains unknown.

### Import Statistics

Below are U.S. import statistics for the natural gums enumerated above for the period 1964 to 1970:

TABLE 1: U.S. IMPORTS OF SOME NATURAL GUMS (1964 to 1970)

<u>Year</u>	<u>Net Quantity (in pounds)</u>	<u>Net Value (in dollars)</u>
1964	68,257,377	14,435,403
1965	83,269,897	15,706,795
1966	87,119,243	16,993,385
1967	77,554,965	16,981,410
1968	64,892,349	15,269,858
1969	68,368,947	18,892,623
1970	73,618,163	21,853,085

Note: The gums included are guar gum, gum arabic, gum tragacanth, karaya gum and locust bean gum.

Source: U.S. Bureau of the Census

In the following tables, statistical breakdowns are given on U.S. imports of some natural gums.

TABLE 2: U.S. IMPORTS OF GUAR GUM (1964 to 1970)

<u>Year</u>	<u>Net Quantity (in pounds)</u>	<u>Net Value (in dollars)</u>
1964	26,688,456	4,069,813
1965	38,066,938	4,440,739
1966	36,319,617	4,621,382
1967	21,207,421	2,840,059
1968	15,106,888	2,098,034

## Market Survey

### POLYVINYL ALCOHOL (PVA)

Rapid growth of fully hydrolyzed PVA for use in polyester-cotton blend warp sizing has caused the PVA market to sharply expand. In the United States especially, demand is considerably greater than the domestic supply for some PVA grades, causing customers, particularly textile manufacturers, to rely a great deal on imports. Competition in the PVA market is extremely intense, with the main competition coming from the Japanese producers. As a result, price weakness has plagued this market over the past few years.

### Applications

TABLE 7: BREAKDOWN BY APPLICATION IN THE UNITED STATES

Textile warp sizing	43%
Adhesives	25%
Paper coating	15%
Miscellaneous	17%

### Producers

TABLE 8: UNITED STATES PRODUCERS

	Capacity*
Air Products & Chemicals, Inc.	30
Borden, Inc.	8
DuPont	15
Monsanto	12
Total	65

\*Millions of pounds annually for PVA not used in manufacture of polyvinyl butyral.

Note: Air Products & Chemicals, Inc. acquired its capacity from Air Reduction (now Airco, Inc.) on January 28, 1971 when it purchased Air Reduction's Chemical and Plastics Division and paid for an 8-year lease on Air Reduction's Calvert City, Kentucky facilities.

Source: Chemical Marketing Reporter, April 1, 1970 and company information.

An important U.S. Producer of PVA for which capacity figures are not available is CPC International, which markets a broad range of fully and partially hydrolyzed grades. Du Pont is building a new PVA plant at LaPorte, Texas, which is expected to be the world's largest PVA plant. It is scheduled to go on-stream in 1972 and should more effectively meet the strong thrust of Japanese competition than has been the case up till now. Japan presently possesses the world's largest capacity of PVA. The main Japanese producers are Denki Kagaku Kogyo K.K., Kuraray Co., Nippon Synthetic Chemical Industry, Shin-Etsu and Unitka Chemical Company. In West Germany, the main producer is Farbwerke Hoechst.

### Price

Price weakness has characterized this market. In the United States, the current price (1972) is \$0.32 per pound delivered for fully hydrolyzed PVA. The high for the period 1957 to 1972 was \$0.67 per pound for fully hydrolyzed grades (bags, truckload, F.O.B. selling point); the low \$0.32 per pound delivered.

## Market Survey

### Growth and Forecasts

For the period 1960 to 1969, it is estimated that overall U.S. PVA consumption has grown at 8% per year. For the period 1969 to 1974, it is expected that consumption will grow at 25% per year. The textile warp size market is expected to provide most of the impetus for the sharp increase in growth. An estimated U.S. production of 1.4 billion pounds of polyester broadwoven goods in 1974 should require 105 million pounds of synthetic size (mostly PVA). The available figures for U.S. production and U.S. sales by original manufacturer are given below:

TABLE 9: U.S. PRODUCTION AND SALES OF PVA (DRY BASIS)

Year	Production (in pounds)	Sales by Original Manufacturer		
		Quantity (in pounds)	Value (in dollars)	Unit Value
1966	38,337,000	37,926,000	16,438,000	\$0.43
1967	43,484,000	37,008,000	16,236,000	0.44
1968	45,168,000	39,083,000	16,555,000	0.42
1969	57,003,000	50,702,000	17,308,000	0.34

Note: Preliminary figures for 1970 show U.S. production at 49,037,000 pounds; sales and use at 39,307,000 pounds.

### CELLULOSE ETHERS

There are many types of cellulose ethers produced and their manufacture is of worldwide scope, which includes many of the Communist-bloc countries (e.g., Czechoslovakia, East Germany, Hungary, Poland and the Soviet Union). Total worldwide production of cellulose ethers is estimated to presently come to 180 million pounds, with sodium carboxymethyl-cellulose (CMC) accounting for approximately 65% and the remainder consisting mainly of the methyl celluloses, ethyl celluloses, hydroxyethylcellulose (HEC) and hydroxypropylcellulose (HPC).

#### Basic Information

The main raw materials for cellulose are wood pulp and cotton linters. These are readily available, which makes the manufacture of cellulose ethers economically attractive. Cellulose itself is not soluble in water. It consists, however, of a polymeric chain of anhydroglucose units, with each anhydroglucose unit possessing three hydroxyl (OH) groups. The hydrogen atoms in the OH groups can, therefore, be replaced under the proper reaction conditions. Thus, when a base, such as aqueous sodium hydroxide, is added, it causes the cellulose molecule to swell. This serves to activate the hydroxyl groups on the cellulose anhydroglucose unit. Various etherification agents can then be added to yield cellulose ethers which are soluble in water.

There are varying degrees of substitution possible up to a maximum of 3. The degree of substitution (D.S.) is sometimes referred to as the degree of etherification. Most commercially available CMC grades fall in the range D.S. 0.4 to 1.2. In the case of HEC, however, in addition to the substitution of hydroxyethyl groups on the cellulose molecule itself, it is possible for the etherification agent ethylene oxide to react with the already substituted hydroxyl groups to form side chains. Therefore, the mols of substitution or molar substitution (M.S.) can be greater than 3. Commercial HEC, however, is usually in the M.S. range 1.8 to 2.5.

## Market Survey

In addition to variations in D.S. or M.S. for the various cellulose ethers, there are variations in the degree of polymerization and purity, as well as other factors (e.g., the pH, the presence of salts and particle size), which yield a wide variety of commercially useful products.

### Production and Sales of Cellulose Ethers

Below are given the available figures for total U.S. production and sales of all cellulose ethers:

**TABLE 11: U.S. TOTAL PRODUCTION AND SALES OF CELLULOSE ETHERS**

Year	Production (in pounds)	Sales by Original Manufacturer		
		Quantity (in pounds)	Value (in dollars)	Unit Value
1963	79,527,000	72,338,000	39,620,000	\$0.55
1964	85,805,000	79,294,000	43,521,000	0.55
1965	91,308,000	85,101,000	46,880,000	0.55
1966	95,933,000	90,523,000	50,489,000	0.56
1967	103,916,000	92,487,000	51,402,000	0.56
1968	117,228,000	106,025,000	58,047,000	0.55
1969	122,419,000	115,807,000	64,615,000	0.56

### SODIUM CARBOXYMETHYLCELLULOSE (CMC)

As a result of the movement towards low phosphate and nonphosphate detergents, the CMC market has recently improved. Prices have firmed considerably compared to the stringent price competition of a few years ago, particularly in the detergent-grade market. Prospects for food-grade CMC look very promising and the food-grade market should grow at twice the anticipated 3% per year growth rate for the overall CMC market in the United States.

In the food area, particularly promising areas are in low-calorie foods and beverages, cake mixes, dehydrated foods, ice cream, pet foods and salad dressings. The paper size and textile warp size markets, however, have not shown growth nor do they look promising. Resistance from other water-soluble polymers in the paper size market has been extremely strong, while CMC has been meeting severe competition from PVA in the textile warp size market.

### Applications

**TABLE 12: BREAKDOWN BY APPLICATION IN THE UNITED STATES**

Detergents	28%
Textiles	24%
Foods	20%
Oil-well drilling muds	10%
Paper sizing	5%
Miscellaneous	13%
Total	100%

### U.S. Producers

It is estimated, by the Chemical Marketing Reporter, November 1, 1971, that of a total U.S. capacity of 71 million pounds per year of CMC, Hercules has the largest capacity at 40 million pounds per year, DuPont is second at 15 million pounds per year and Procter & Gamble's Buckeye Cellulose Corporation is third at 7 million pounds per year.

## Market Survey

### Price

In the United States, for the period 1952 to 1972, the high price was \$0.45 per pound (crude, low or medium viscosity, bags, 23,000 pounds, delivered East of the Rocky Mountains, 100% basis); the low price, \$0.37 per pound (same basis). The current price (1972) is \$0.45 per pound (same basis), with sales to detergent manufacturers at \$0.38 per pound (carlot, same basis).

### Growth and Forecasts

For the period 1960 to 1970, growth of the overall U.S. CMC market (in terms of consumption) was 3.8% per year, with growth expected to fall to a 3% rate for the period 1970 to 1975. Some areas of the market, however, should grow above this rate. The large soap and detergent manufacturers (e.g., Procter & Gamble, Lever Bros. and Colgate-Palmolive) are looking for detergent systems that can meet the antipollution requirements which have been established by some municipalities and which are in the process of being formulated by others. CMC could benefit, but there has as yet been no strong movement in any one direction regarding such systems. Another market that holds promise for future growth is use of CMC as a soil-release agent in wash-and-wear garments. At this time, the food market shows the greatest tangible potential for growth. In the oil-well drilling mud market, CMC has been losing ground to the lignosulfonates and can be expected to continue to do so, unless some significant technological breakthrough takes place. Figures for U.S. production and U.S. sales by original manufacturer are given below for the period 1960 to 1969:

TABLE 13: U.S. PRODUCTION AND SALES OF CMC (100%)

Year	Production (in pounds)	Sales by Original Manufacturer		
		Quantity (in pounds)	Value (in dollars)	Unit Value
1960	42,660,000	38,310,000	17,711,000	\$0.46
1961	47,604,000	41,665,000	18,984,000	0.46
1962	43,488,000	41,119,000	18,298,000	0.44
1963	42,741,000	41,495,000	18,532,000	0.45
1964	44,930,000	42,454,000	18,712,000	0.44
1965	48,770,000	45,242,000	19,057,000	0.42
1966	48,736,000	48,355,000	20,758,000	0.43
1967	54,750,000	50,816,000	21,290,000	0.42
1968	59,951,000	58,605,000	24,750,000	0.42
1969	61,586,000	62,349,000	26,254,000	0.42
