To *Donnie* and *Ronnie*—
they never understood
why Daddy worked so hard,
and to *Candy* and *Kathy*—
who also suffered without complaint.

PREFACE

This book is a comprehensive treatment of the theories, algorithms, and computational nature of deterministic network flows. The book was developed from 10 years of classroom lecture notes compiled by ourselves, numerous technical articles, and contributions from leading experts in the field. The fundamental contribution of this textbook is a simple, practical approach to the design and implementation of network-flow algorithms. At the risk of criticism from fellow colleagues, we have sometimes sacrificed theoretical development and mathematical proofs for explanation by way of computational presentations. When appropriate, each technique is first presented as a mathematical programming problem, and then followed by an algorithmic procedure that guarantees problem resolution through faster and more efficient computational techniques as compared to direct use of mathematical models. Every algorithm is used to solve one or more real-world examples. A practical feature of the book is the documentation and listing of a FORTRAN IV network optimization computer program that can be used either for teaching or research purposes, on small- to medium-sized problems.

This book is intended to be an introductory treatment of network flows, and should prove useful as a textbook in a first course in network analysis at either the undergraduate or graduate level. The treatment is self contained, and no particular degree of mathematical sophistication is necessary to

understand the material developed in this book. Limited exposure to linear programming notation and FORTRAN programming would enhance the learning experience, but are not necessary to understand the algorithms as presented.

It has been our pleasure during the last 10 years to note a major explosion in the interest and application of network-flow algorithms. There does not seem to be an educational area that does not embrace network analysis; its applications are continuously surfacing in business administration, all fields of engineering, transportation analysis, project planning and control, sequencing and scheduling, and other areas too numerous to mention. The basic appeal is the great flexibility of network representation and the visual/graphical interpretation of network models. In addition, network solution procedures have recently been developed that are significantly more efficient than conventional linear programming.

The major barrier to widespread acceptance and use of network analysis is undoubtedly technical communication. With only a few exceptions, prior publications in the field and major developments have been presented through a mathematical programming or graph theoretic base. These results have usually surfaced in technical articles or sophisticated reports. This book attempts to avoid some of the theoretical and mathematical sophistication and present the fundamental aspects of network-flow analysis in a non-technical fashion.

The book is divided into five basic chapters and one appendix. Chapter 1 presents the notation and symbolism used throughout the text, and establishes definitions that pertain to developments in latter chapters. Chapter 2 is a comprehensive treatment of deterministic network flows, and begins with a presentation of several examples illustrating network formulations of practical problems. Chapter 2 utilizes a wide range of examples and introduces FORTRAN IV computer programs to aid practical solution of larger problems. Chapter 3 presents a unified and comprehensive treatment of the elegant out-of-kilter algorithm, and contains a detailed development of the theoretical and computational aspects of this powerful technique. Numerous applications are suggested in this chapter, and several example problems are used to illustrate modeling procedures. Chapter 4 is a complete treatment of project management and control procedures based upon PERT and CPM. Computational procedures, resource balancing/leveling, and computerized procedures are thoroughly discussed in this chapter. Chapter 5 is a treatment of more advanced topics, including networks with gains and losses, GERT procedures for special forms of stochastic networks, and multicommodity network flows. The Appendix provides a complete listing and operating instructions for the network optimization program.

We have attempted to draw upon the knowledge and expertise of many individuals in this field. Indeed, several have contributed directly to

the material contained in this text. Portions of Chapter 2, particularly many of the applied examples, were contributed by Dr. G. E. Bennington. Portions of Chapter 3, dealing with the out-of-kilter algorithm, were taken from original lecture notes by Dr. Paul A. Jensen, and several examples were contributed by Dr. R. E. D. Woolsey and Dr. Hunter Swanson. Dr. Warren Thomas contributed most of the material on the computational aspects of PERT/CPM in Part I of Chapter 4. The entire section dealing with resource control in Chapter 4 was contributed by Dr. Edward Davis, and the computer software survey in Chapter 4 was taken from an article by Dr. Larry A. Smith and Mr. Peter Mahler. Material in Chapter 5 dealing with the theory of generalized networks was adopted from original research by Drs. Gora Bhaumik and Paul Jensen, with several examples cited from works of Dr. Darwin Klingman and Dr. Fred Glover. Theories and computational aspects of GERT are attributed to Dr. A. Alan B. Pritsker. Finally, the material on multicommodity network flows was contributed totally by Dr. James Evans.

In addition to direct individual contributions in Chapters 3 and 4, this book obviously depends upon and draws from technical material developed by many of our fellow colleagues, too numerous to acknowledge. They will recognize their individual contributions. We are grateful to have benefited from their work. In conclusion, we would like to specifically acknowledge the individual contributions of Dr. Paul A. Jensen and Dr. R. E. D. Woolsey. They will understand and accept our special recognition for their unique support in writing this book. The one individual who deserves grateful accolades for his comprehensive criticisms and contributions to this book is Dr. James Evans. Dr. Evans reviewed our first draft and supplied many important suggestions, for which we are very grateful. We would also be remiss if we didn't thank Mrs. Jan Bertch and Mrs. Candy Phillips for typing preliminary drafts of this manuscript, and suffering through dozens of angry outbursts as the material was composed. Last but not least, we are indebted to the American Institute of Industrial Engineers for permission to reproduce printed material.

CONTENTS

Preface	xiii
1 Introduction	2
1.1 Definitions, Notation, and Symbolism	5
1.2 Matrix Representation of Networks	11
1.3 Conservation of Flow	14
1.4 Contribution of the Maximum-Flow Minimum-Cut Theorem	15
2 Deterministic Network Flows	22
2.1 Applications of Network-Flow Models	24
2.1.1 Equipment Replacement	24
2.1.2 Project Planning	25
2.1.3 Scheduling Tanker Voyages	26
2.1.4 The Maximum-Flow and Minimum-Cost Flow Problems	27
2.1.5 The Transportation Model	29
2.1.6 A Caterer Problem	30
2.1.7 Employment Scheduling	31
2.1.8 A Fleet Scheduling Problem	32
2.1.9 A Production Planning Model	35
2.1.10 Conclusions	37

2.2	Linear Programming and Its Relationship to Network Flows	39
2.3	The Shortest-Route Problem—Dijkstra's Algorithm	46
2.3.1	An Iterative Procedure	47
2.3.2	Example of Dijkstra's Algorithm	47
2.3.3	Shortest-Route Problem: Buying a New Car	49
2.3.4	Computer Code for Dijkstra's Algorithm	51
2.3.5	A Problem in Oil Transport Technology	52
2.4	Multiterminal Shortest-Chain Route Problems	53
2.4.1	Example of the Multiterminal Shortest-Chain Problem	56
2.4.2	Multiterminal Shortest-Route Problem: Design of a Mail Distribution System	61
2.4.3	Computer Code for the Multiterminal Shortest-Route Algorithm	64
2.4.4	Routing of Rail Cars	65
2.5	Shortest-Path Models with Fixed Charges	68
2.6	The K -Shortest-Path Problem	72
2.6.1	The Double-Sweep Method	73
2.6.2	Sample Problem for the Double-Sweep Method	77
2.6.3	Computer Code for the Double-Sweep Algorithm	82
2.6.4	Computational Results	84
2.6.5	Computer Example for a Four-Shortest Path Problem	86
2.7	Analysis and Complexity of Shortest-Path Algorithms	88
2.7.1	Computational Complexity of Dijkstra's Method	89
2.7.2	Computational Complexity of Floyd's Algorithm	89
2.7.3	Computational Complexity of the Double-Sweep Method	90
2.8	Minimal Spanning Tree Problems	91
2.8.1	Minimal Spanning Trees—Computational Procedure	91
2.8.2	Example of a Greedy Solution	92
2.8.3	Computer Code for the Minimal Spanning Tree Algorithm	94
2.8.4	Allocation of Highway Maintenance Funds	95
2.8.5	Applications of Minimal Spanning Trees	96
2.9	The Traveling Salesman Problem	97
2.9.1	Construction of a Lower Bound	98
2.9.2	Branching	101
2.9.3	Computational Procedure	101
2.9.4	Final Remarks	106
2.9.5	Computer Code for the Traveling Salesman Algorithm	108
2.9.6	Scheduling International Travel	109
2.10	The Transportation Problem	111
2.10.1	Mathematical Model	112
2.10.2	The Transportation Simplex Algorithm	115

2.10.3	A Network Interpretation for the Transportation Simplex Algorithm	126
2.10.4	A Production-Distribution Model	128
2.11	The Transshipment Problem	130
2.12	The Assignment Problem	132
2.12.1	Mathematical Model	132
2.12.2	The Hungarian Algorithm	133
2.12.3	Example of the Hungarian Algorithm	135
2.12.4	Remarks	139
2.12.5	A Product-Plant Allocation Problem	139
2.13	The Assignment Problem and the Traveling Salesman Problem	141
2.14	The Maximum-Flow Problem	144
2.14.1	A Labeling Procedure for the Maximum-Flow Algorithm	146
2.14.2	Example of the Labeling Algorithm	147
2.14.3	The Maximum Flow/Minimum Cut Theorem	149
2.14.4	Design of a Centralized Sewage Waste Treatment Plant	151
2.14.5	Computer Code for the Maximum-Flow Algorithm	155
2.14.6	A Problem in Grain Shipment and Storage	156
2.15	The Multiterminal Maximal-Flow Problem	158
2.15.1	The Gomory-Hu Algorithm	159
2.15.2	Justification of the Algorithm	160
2.15.3	Example of a Multiterminal Maximal-Flow Problem	162
2.16	The Multiterminal Maximum-Capacity Chain Problem	165
2.16.1	Optimal Movement of Bulk Freight	167
2.16.2	Computer Code for the Multiterminal Maximum-Capacity Route Algorithm	172
2.16.3	Transporting the Space Shuttle	173
2.17	Node and Arc Failures in Networks	179

3 The Out-of-Kilter Algorithm: Generalized Analysis of Capacitated, Deterministic Networks 204

Part I: Network-Flow Optimization with the Out-of-Kilter Algorithm—Theoretical Concepts 205

3.1	Basic Terminology	206
3.2	Basic Theory	208
3.3	Fundamental Theorems	212

3.4	The Out-of-Kilter Algorithm for Solution of Minimal-Cost Circulation Problems*	213
3.5	The Labeling Procedure	214
3.6	A Graphical Interpretation of the Out-of-Kilter Algorithm	219
3.6.1	Horizontal Displacements	220
3.6.2	Vertical Displacements	222
3.7	Algorithmic Steps	223
3.8	A Numerical Example	224
3.8.1	A Numerical Example for the Out-of-Kilter Algorithm	224
3.9	Summary and Conclusions	229
Part II: Network Flow Optimization with the Out-of-Kilter Algorithm—Modeling Concepts		230
3.10	Problem Solution Using the Out-of-Kilter Algorithm	230
3.11	The Transportation Problem	231
3.11.1	Example of the Transportation Formulation	233
3.12	The Assignment Problem	234
3.12.1	Example of the Assignment Formulation	234
3.13	Maximum Flow Through a Capacitated Network	235
3.14	The Shortest-Path Problem	235
3.15	The Shortest-Path Tree Problem	236
3.16	The Transshipment Problem	237
3.17	Nonlinear Costs	238
3.18	A Production-Distribution Problem	239
3.19	Summary and Conclusions	246
Part III: Application of the Out-of-Kilter Algorithm		247
3.20	The “Bottleneck” Assignment Problem	247
3.21	Scheduling Workers to Time-Dependent Tasks	250
3.22	A Wholesale Storage and Marketing Problem	252
3.23	Computer Code for the Out-of-Kilter Algorithm	254
3.24	Crude Oil Production and Distribution	255
4 Project Management Procedures		268
Part I: Project Management with CPM and PERT		269
4.1	Origin and Use of PERT	270
4.2	Origin and Use of CPM	271
4.3	Problem Characteristics	271
4.4	Network Construction	273
4.4.1	A Manufacturing Problem	275
4.5	Earliest Possible Times for Each Event	276

4.6	Latest Allowable Times for Each Event	277
4.7	Slack Times and the Critical Path	278
4.8	Tabular Calculation of the Early Start and Latest Finish Times	279
4.9	Four Float Measures for Critical Path Scheduling	281
4.9.1	The Computational Procedure	281
4.9.2	Float Calculations	283
4.9.3	Free Float	285
4.9.4	Independent Float	285
4.9.5	Safety Float	286
4.10	An Activity-on-Node Formulation	287
4.10.1	Network Construction	287
4.10.2	Computational Procedure	288
4.11	Program Evaluation and Review Technique (PERT)	291
4.11.1	A PERT Example	293
4.11.2	Probabilities of Completing the Project	294
Part II:	Resource Allocation in Project Networks	295
4.12	Time vs. Cost: Dollar Allocations	296
4.12.1	A Flow-Network Algorithm for Time/Cost Trade-offs in CPM Projects	300
4.12.2	Applications of Time/Cost Procedures	314
4.13	Resource Loading	316
4.14	Resource Leveling	318
4.15	Fixed Resource Limits	320
4.16	Constrained Resources	322
4.16.1	Heuristic Approaches	322
4.16.2	Optimal Approaches	324
Part III:	A Comparison of Commercially Available CPM/PERT Computer Programs	327
5	Advanced Topics	342
Part I:	Generalized Networks—Networks with Gains and Losses	343
5.1	Application of Generalized Networks	344
5.2	GNP as a Linear Programming Problem	345
5.3	Network Characteristics	346
5.4	Case I: Generalized Networks with No Flow-Generating or Flow-Absorbing Cycles	347
5.4.1	Example Formulation	348
5.5	Case II: Generalized Networks with Flow-Generating and/or Flow-Absorbing Cycles	350
5.5.1	Phase I: Initial Flow	350
5.5.2	Phase II: The Marginal Network	350
5.5.3	Phase III: The Flow-Augmentation Process	351

5.6	Phase I: The Minimum-Cost Flow-Augmenting Chain	351
5.7	Phase II: Constructing the Marginal Network	352
5.8	Phase III: Executing the Flow-Augmentation Process	353
5.9	A Numerical Example with Gains and Losses	355
5.10	Summary and Conclusions	362
Part II:	Stochastic Networks—Graphical Evaluation and Review Technique (GERT)	363
5.11	Network Representation	363
5.11.1	Input Functions	364
5.11.2	Output Functions	364
5.12	GERT Basic Procedures	365
5.12.1	Arcs in Series	367
5.12.2	Branches in Parallel	368
5.12.3	Self-Loops	368
5.13	Basic Concepts of Flowgraphs	370
5.14	Definitions	371
5.15	Mason's Rule for Closed Flowgraphs	373
5.16	Mean and Variance Calculation	376
5.17	GERT Applications	376
5.17.1	Production of a High-Risk Item	376
5.17.2	Material Processing	377
5.17.3	Determination of Probabilistic Time Standards for Tasks Performed under Uncertainty	380
Part III:	Multicommodity Network Flows	386
5.18	Linear Programming Formulations	388
5.19	A Special Class of Integer Multicommodity Networks	390
5.19.1	Shipment of Automotive Transmissions	392
5.20	Approximate Solution of Multicommodity Transportation Problems through Aggregation	393
5.20.1	A Fruit Distribution Problem	397
5.21	Error Bounds for Aggregation	398
5.22	Maximal Flows in Multicommodity Networks	400
5.23	Multicommodity Flows in Undirected Networks	403
5.23.1	A Two-Commodity Flow Problem	407
5.24	Maximal Flows and Funnel Nodes	409
5.25	Applications of Multicommodity Networks	410
5.25.1	Tanker Scheduling	411
5.25.2	Urban Transportation Planning	412
5.25.3	Computer-Communication Models	413
5.26	Notes and Remarks	414
Appendix	The Network Optimization Computer Code (NETOPT)	425
Index	467	

FUNDAMENTALS OF NETWORK ANALYSIS

INTRODUCTION

“Cheshire-Puss”, she began, rather timidly,

*“Would you tell me, please, which way I
ought to go from here” ?*

*“That depends a great deal on where you
want to get to”, said the cat.*

“I don’t much care where—,” said Alice.

*“Then it doesn’t matter which way you go,”
said the cat.*

“—so long as I get somewhere,” Alice added.

From Alice in Wonderland

Lewis Carroll

As the Cheshire Cat so astutely observed in Wonderland, progress can often be made if one wanders around long enough. However, there are often better ways to search for an optimal solution than the aimless wandering of Alice. Network modeling techniques often provide the framework and computational structure to greatly improve many traditional approaches to systems analysis. The purpose of this chapter is to present the necessary machinery to both understand and apply the fundamental algorithms pre-

1

sented in this text. Of course, the application of network analysis techniques often requires not only "where you want to get to" but also "which way you ought to go." Hopefully, this chapter will aid in defining both strategies.

A modern society can be viewed, in part, as a system of networks for transportation, communication, and distribution of energy, goods, and services. The complex structure and cost of these subsystems demand that existing facilities be efficiently used and that new facilities be rationally designed. Network analysis techniques can be of great value in the design, improvement, and rationalization of complex large-scale systems.

Network-flow models and solution techniques provide a rich and powerful framework from which many engineering problems can be formulated and solved. The visual and logical structure of network-flow analysis often provides a fresh and natural approach from which further engineering analysis can proceed. Once only a small segment in the field of operations research, network analysis techniques have recently emerged as a viable and computationally tractable approach to solving significant problems faced by modern engineering analysts.

The origins of network analysis are old and diverse. Network analysis relies heavily on graph theory, a branch of mathematics that evolved with Leonhard Euler's formulation and solution of the famous Königsberg bridge problem in 1736 [7]. More than a century later, James Clerk Maxwell and

Gustav Robert Kirchhoff discovered certain basic principles of network analysis in the course of their studies of electric circuits. Since then, network analysis has become an important tool in the investigation of electrical systems. Early in the twentieth century, telephone engineers in Europe and the United States devised network methods to determine the best capacity of telephone trunk lines and switching centers in order to guarantee specified levels of customer serviceability. In the 1940s, during the period of World War II, the development of operations research yielded a number of techniques for the mathematical study of large-scale systems. Pioneering work in modern network analysis was conducted by Hitchcock [11] in 1941 and Koopmans [15] in 1947. Since then, network analysis has been a very active and productive research area with well over 1000 published papers. The emphasis of research in the 1950s and early 1960s was on formulation of new models and development of new algorithms. Later, emphasis shifted to the extension, computer implementation, and analysis of previously developed models and algorithms. Survey papers have been written by Fulkerson [10], Elmaghraby [6], Bradley [2], and Magnanti and Golden [16], among others. As the field of network analysis has developed over the years, the need has arisen for updated books providing different orientations at various levels of discussion. Books with extensive treatment of networks have been contributed by Ford and Fulkerson [8], Charnes and Cooper [4], Dantzig [5], Busacker and Saaty [3], Hu [12], Frank and Frisch [9], Whitehouse [21], and, more recently, Jensen and Barnes [14], Bazarra and Jarvis [1], and Minieka [17].

Network models and analysis are widely used in operations research for diverse applications, such as the analysis and design of large-scale irrigation systems, computer networks, cable television networks, transportation systems, and ground and satellite communication networks. Efficient network methodologies have been implemented to solve industrial problems, such as the warehousing and distribution of goods, project scheduling, equipment replacement, cost control, traffic studies, queueing analysis, assembly-line balancing, inventory control, and manpower allocation, to name a few.

Pritsker [20] provides some insight as to the recent surge in the application of network analysis techniques:

Networks and network analyses are playing an increasingly important role in the description and improvement of operational systems primarily because of the ease with which systems can be modeled in network form. This growth in the use of networks can be attributed to:

1. The ability to model complex systems by compounding simple systems.
2. The mechanistic procedure for obtaining system figure-of-merits from networks.

3. The need for a communication mechanism to discuss the operational system in terms of its significant features.
4. A means for specifying the data requirements for analysis of the system.
5. A starting point for analysis and scheduling of the operational system.

Item 5 was the original reason for network construction and use. The advantages that accrued outside of the analysis procedure soon justified the network approach. Considerable work is motivated by the need for extending present analysis procedures to keep pace with applications of networks.

Network analysis is not a discipline confined to only one branch of academia or industry. Indeed, the real strength of the network approach lies in the fact that it can be successfully applied to almost any problem when the modeler has enough knowledge and insight to construct the proper network representation. The advantages of using network models can be stated as follows:

1. Network models accurately represent many real-world systems.
2. Network models seem to be more readily accepted by nonanalysts than perhaps any other type of models used in operations research. This phenomenon appears to stem from the notion that "a picture is worth a thousand words." Managers seem to accept a network diagram more easily than they do abstract symbols. Additionally, since network models are often related to physical problems, they can be easily explained to people with little quantitative background.
3. Network algorithms facilitate extremely efficient solutions to some large-scale models.
4. Network algorithms can often solve problems with significantly more variables and constraints than can be solved by other optimization techniques. This phenomenon is due to the fact that a network approach often allows the exploitation of particular structures in a model.

1.1 Definitions, Notation, and Symbolism

A *network* consists of a set of *nodes* and a set of *arcs* connecting the nodes. The nodes are also referred to as vertices or points. The arcs are also called edges, links, lines, or branches. A network can be represented by the notation $G = (N, A)$, where N is the set of nodes and A the set of arcs of the network G .
