Introduction

With the appearance of Volume 3 of this Specialist Periodical Report, we begin to feel that 'Photochemistry' is becoming an established publication. The increase in length noted in Volume 2 has continued this year, but on a reduced scale, and we are optimistic that in the future we shall be able to stabilize at something like the present length without retreating from our present aim to cover essentially the whole of non-biological photochemistry in a single volume.

The general plan has been continued without significant alteration in this Volume, and we are glad to welcome Dr. B. H. Orger and Dr. D. H. Slater to the team of Reporters. Dr. Slater has contributed a section on Atmospheric Photochemistry which should be of interest to the growing number of chemists who are studying the photochemical aspects of air pollution. It is hoped to expand this section somewhat in Volume 4.

As always, we shall be grateful to be informed of any errors or major omissions which readers may discover.

D. B.-S.

Contents

Part I Physical Aspects of Photochemistry

Chapter 1 Spectroscopic and Theoretical Aspects

By D. Phillips

- | | |
|---|-----------|
| 1 Absorption Spectra and MO Calculations | 3 |
| 2 Theoretical Aspects of Non-radiative Transitions | 43 |
| 3 Theoretical Aspects of Photoreactions | 62 |
| 4 CIDNP Studies | 68 |

Chapter 2 Developments in Instrumentation and Techniques 70

By M. A. West

Chapter 3 Photophysical Processes in Condensed Phases

By D. Phillips

- | | |
|--|-----------|
| 1 Fluorescence and Fluorescence Quenching | 95 |
| Spin-Orbit Coupling | 117 |
| Charge-transfer Interactions | 119 |
| Excimers | 128 |
| Other Fluorescence Quenching | 130 |
| Temperature Effects | 132 |
| Delayed Fluorescence | 134 |

2 Aspects of the Triplet State	147
Triplet-Triplet Absorption	147
Phosphorescence	149
Phosphorescence Decay Times	151
Quenching of Triplet States	160
Magnetic and Microwave Studies on Triplet States	161
3 Electronic Energy Transfer	164
4 Physical Aspects of Photochemical Reactions in Solution	170
Laser Studies	170
Dyestuffs	172
Ketones	174
Miscellaneous	175
Photochromic Compounds	179
5 Photochemistry of Solids	185
Physical Processes	185
Reactions in Solids	187
Adsorbed Molecules	189
Chapter 4 Gas-phase Photochemistry <i>By D. Phillips and D. H. Slater</i>	
1 Aromatic Molecules	191
2 Alkanes and Olefins	222
Alkanes	222
Olefins	229
3 Atom-sensitized Reactions	241
4 Carbonyl Compounds	250
5 Nitrogen-containing Compounds	262

<i>Contents</i>	vii
6 Sulphur-containing Compounds	265
7 Halogen-containing Compounds	269
8 Atmospheric Photochemistry	275

Part II Inorganic Photochemistry
By D. Phillips

1 Water and Hydrogen Peroxide	293
2 Photochemistry of Anions	297
3 Metal Co-ordination Compounds and Salts	307
Cobalt Complexes	311
Chromium Complexes	316
Iron Complexes	325
Platinum Complexes	327
Rhodium Complexes	329
Iridium Complexes	333
Ruthenium Complexes	336
Manganese	338
Molybdenum	340
Copper	341
Miscellaneous	341
Uranyl and Rare-earth Ions	343
Organometallic Compounds	347
4 Gas-phase Studies	353
5 Solid State, including Phosphors	359
Silver Halides	359
Calcium Fluoride	359
Cadmium Sulphide	360
Miscellaneous	361

Part III Organic Aspects of Photochemistry

Chapter 1 Photolysis of Carbonyl Compounds*By W. M. Horspool*

1 Norrish Type I Reactions	369
2 Norrish Type II Reactions	382
3 Rearrangement Reactions	400
4 Oxetan Formation and Addition Reactions	405
5 Fragmentation Reactions	410
Decarbonylation	410
Decarboxylation	412
Miscellaneous Fragmentations	416

**Chapter 2 Enone Rearrangements and Cycloadditions:
Photoreactions of Cyclohexadienes, Quinones,
Tropones, etc.***By W. M. Horspool*

1 Cycloaddition Reactions	423
Intermolecular	423
Intramolecular	429
2 <i>cis-trans</i> Isomerization of Enones	430
3 Enone Rearrangements	437
Cyclohexenones	440
Miscellaneous Enones	443
4 Dimerization and Intramolecular Addition Reactions	450
5 Photoreactions of Thymine, etc.	459

6 Photochemistry of Dienones	462
Linearly-conjugated Dienones	462
Cross-conjugated Cyclohexadienones	464
Other Dienones	474
7 1,2-, 1,3-, and 1,4-Diketones, etc.	477
1,2-Diketones	477
1,3-Diketones	482
1,4-Diketones	484
Anhydrides	487
1,5-Diketones	489
8 Quinones	491
<i>p</i> -Quinones	491
<i>o</i> -Quinones	494
9 Tropones and Tropolones	496

Chapter 3 Photochemistry of Olefins, Acetylenes, and Related Compounds

By W. M. Horspool

1 Reactions of Alkenes	498
Addition Reactions	498
Hydrogen Abstraction Reactions	501
<i>cis-trans</i> Isomerization	502
Rearrangement Reactions	505
2 Reactions involving Cyclopropane Rings	508
Di- π -methane Rearrangements	514
Other Reactions involving Cyclopropane Rings	517
3 <i>cis-trans</i> Isomerization of Dienes	523

4 (2 + 2) Intermolecular Cycloaddition Reactions and Valence-bond Isomerizations of Dienes	525
5 Reactions of Trienes and Higher Polyenes	531
6 Reactions of Carbonium Ions and Zwitterionic Species	534
7 Photolysis of Insecticidal Chlorocarbons and Related Compounds	538
8 (2 + 2) Intramolecular Addition Reactions	540
9 Dimerization and Intermolecular Cycloaddition Reactions	545
10 Cycloaddition Reactions of Acenaphthylene	548
11 Reactions of Acetylenic Compounds	552
12 Miscellaneous Fragmentation Reactions	555
Chapter 4 Photochemistry of Aromatic Compounds <i>By A. Gilbert</i>	
1 Isomerization Reactions	559
2 Addition Reactions	568
3 Substitution Reactions	577
4 Cyclization Reactions	585
5 Dimerization Reactions	609
6 Lateral-nuclear Rearrangements	611
7 Furan, Thiophen, and Pyrrole Photochemistry	618

Chapter 5 Photo-oxidation and -reduction Reactions
By B. H. Orger

1 Conversion of C=O into C—OH	621
2 Reduction of Nitrogen-containing Compounds	644
3 Oxidation of Nitrogen-containing Compounds	656
Chlorophyll Photochemistry	663
4 Photo-oxidation of Aromatic Substances	665
5 Oxidation of Aliphatic Unsaturated Compounds	674
6 General Singlet Oxygen Properties and Miscellaneous Oxidations	684

Chapter 6 Photoreactions of Compounds containing Hetero-
atoms other than Oxygen
By B. H. Orger

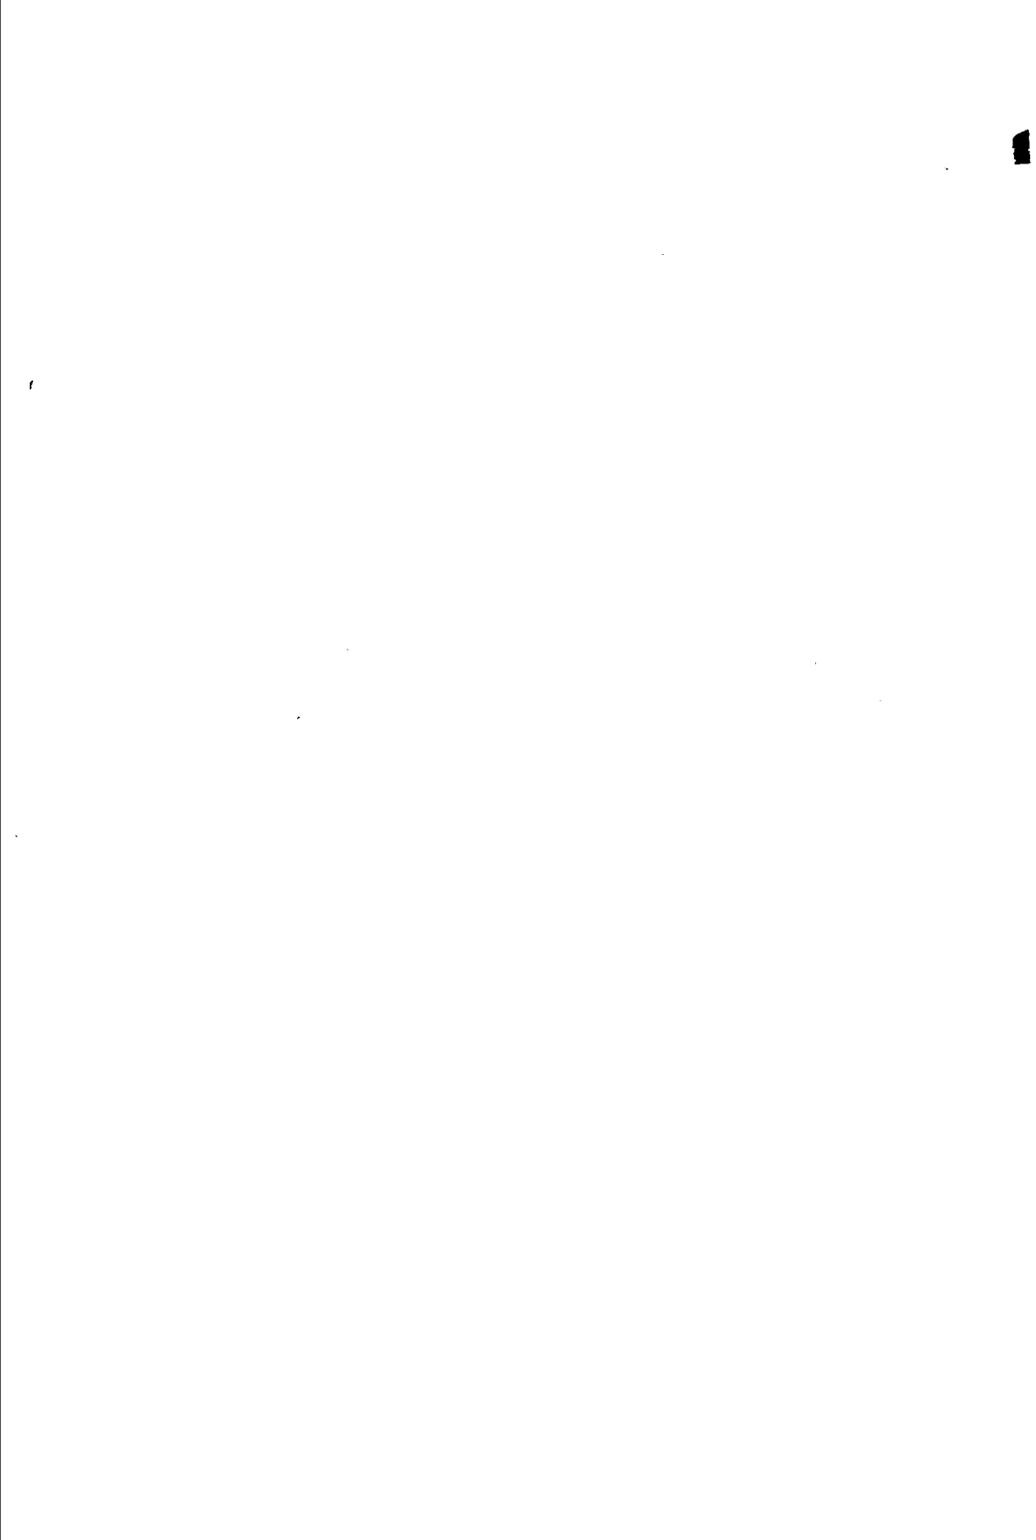

1 Nitrogen-containing Compounds	691
<i>N</i> -Oxide Rearrangements	691
Intramolecular Cyclization and Ring-contraction Reactions	698
Reactions of Five-membered Heterocyclic Nitrogen Compounds	702
General Rearrangement Reactions	706
Substitution Reactions	716
Addition Reactions	717
General Synthetic Reactions	724
Miscellaneous Reactions	728

2 Sulphur-containing Compounds	731
3 Other Heteroatom Compounds	739
Chapter 7 Photoelimination Reactions <i>By A. Gilbert</i>	
1 Elimination of Nitrogen from Azides	745
2 Decompositions of Diazo-compounds	753
3 Decomposition of Azo-compounds	758
Acyclic Compounds	758
Cyclic Azo-compounds	761
4 Decomposition of other Compounds with N—N Bonds	771
5 Loss of the Elements of Carbon Dioxide	774
6 Fragmentation Reactions of Organosulphur Compounds	779
7 Miscellaneous Decomposition and Elimination Reactions	792
Part IV Polymer Photochemistry <i>By D. Phillips</i>	
1 Photopolymerization	807
2 Cross-linking, Graft Polymerization, and Photoreactive Polymers	823
3 Optical Properties of Polymeric Systems	825

<i>Contents</i>	xiii
4 Photodegradation	846
Polyolefins	846

Vinyl Polymers	854
Cellulose	855
Miscellaneous	855
Ancillary Reports	856
Errata	858
Author Index	860

Part I

PHYSICAL ASPECTS OF PHOTOCHEMISTRY

The work reported in this section is categorized as in Volume 2 together with an additional section on Chemically Induced Dynamic Nuclear Polarization, a subject which is of increasing interest to photochemists. The restriction on the number of papers considered in Section 1 has been even more severe this year, and those selected for inclusion must inevitably represent a subjective selection by the authors from the very large number available. Nevertheless, it is hoped that those included are of interest to photochemists, and that those excluded on the grounds of space-saving are of less current general interest, although inevitably some of those excluded will have been of interest to particular groups and individuals working in the field.

1 Absorption Spectra and MO Calculations

The absorption spectrum of diatomic argon has been investigated in the 780–1080 Å region with a 6.65-m normal incidence vacuum spectrograph using the helium and argon continua as background sources. Nine discrete band systems were identified.¹ The analysis shows that the ground state is stable, has a dissociation energy $D_0^0 = 76.9 \text{ cm}^{-1}$, and six vibration levels, $v = 0-5$. A number of previous calculations of intramolecular potentials agree with these experimental results. Definite dissociation products are assigned for some of the upper states of these systems. A triplet potential surface for argon has been calculated,² and Wanner-type impurity excited states in liquid rare gases reported.³

It has been shown that the gross shifts in the spectrum of the Hg $^3P_1 \leftarrow ^1S_0$ transition of Hg in solid rare gases can be correlated by considering the difference in the interaction potential between the lattice and the Hg atom in the 3P_1 and 1S_0 states, providing the distortion of the lattice caused by the Hg atom is taken into account.⁴ In Ar, Kr, and Xe the spectrum can consist of three separate components. It was quantitatively shown that one component arises from relatively isolated Hg atoms, the other two from Hg atoms having nearest neighbour Hg atoms. This interpretation has been criticized,⁵ and an alternative suggested in which

the two additional absorption components arise from splitting of the 3P_1 state of Hg by the asymmetry of the crystal field caused by a vacancy adjacent to the Hg atom. The latter interpretation is itself subject to several criticisms.⁶ The intensities of the two additional components relative to the main component depend on the Hg doping concentrations³ as predicted by the Hg-adjacent-Hg hypothesis but not by the Hg-vacancy hypothesis. In addition, there is no obvious reason why the equilibrium concentration of a Hg-vacancy complex should greatly exceed the fractional concentration of vacancies in pure rare gases at equilibrium. On energetic grounds the reverse would be more likely. Since the equilibrium mole fraction of vacancies is about 0.015 at the triple point of Ar and Kr, and since for Ar the equilibrium value of about 10^{-4} can be attained rapidly at 50 K, it would be surprising if the ratio of substitutional Hg to Hg-adjacent vacancy exceeded 0.1, whereas at least this fraction is necessary to explain the observed relative intensities.

A semi-empirical treatment has generated potential energy curves of the hydrogen molecule in the ground $^1\Sigma_g$ and excited $^3\Sigma_u$ states.⁷ A spectroscopic study of deuterium photolysis has been reported.⁸

Hartree-Fock (HF) electronic transition moments have been calculated⁹ in both the position and momentum representations, and were presented as a function of the internuclear separation R for the BeH, MgH, OH, and SH ($A-X$) systems. The vibrational averages of these quantities were obtained and the results used to calculate some absorption band oscillator strengths. For the OH ($A-X$) system several independent experimental determinations of the 0-0 band oscillator strength have been reported in the literature, and the theoretical value of 20.6×10^{-4} differs from experiment by a factor of 2.5. Consideration of the united and separated atom limits and the region of the equilibrium internuclear separation for the states involved leads to an abbreviated discussion of the effect of correlation on the HF transition moments. HF transition moment calculations at a single value of R were also reported for the BH⁺, AlH⁺, HF⁺, and HCl⁺ ($A-X$) systems.

By means of a photoelectrical technique,¹⁰ the absorption cross-section of the O₂ continuum in the region 2350–1814 Å and the absorption cross-section of CO₂ in the region 2160–1718 Å have been measured. The cross-section of the O₂ continuum is 3.8×10^{-24} cm² at 2350 Å; it slowly increases towards shorter wavelengths and reaches 10.7×10^{-24} cm² at about 1980 Å, then increases very rapidly and reaches 7.1×10^{-22} cm² at about 1814 Å. In the case of CO₂, numerous discrete bands were found overlapping a weak continuum in the wavelength region below 1980 Å. The absorption cross-section of the CO₂ continuum is about 2×10^{-24} cm².

at 2100 Å; it gradually increases toward the shorter wavelength side, and reaches about $4 \times 10^{-24} \text{ cm}^2$ at 2000 Å. The continuum rises rapidly at 2000 Å and its value is $1.19 \times 10^{-20} \text{ cm}^2$ at 1718 Å.

Absorption coefficients of $^1\Delta_g\text{O}_2$ have also been measured in the far u.v.¹¹ Measured lifetimes of rotational and vibrational levels of electronic states of N_2 have been reported.¹² Vacuum-u.v. spectroscopy and photoelectron spectroscopy have been used to determine the electronic structure of NO_2 ,¹³ and the results correlated with Gaussian orbital calculations. These results may be compared with those calculated by other workers.¹⁴

It has been demonstrated by photofragment spectroscopy that the long-accepted assignment of the main I_2 visible continuum as being almost entirely due to a transition to the $B\text{O}^+u(^3\Pi)$ state is incorrect. In reality, a transition to a $1u$ state, probably the $1u(^1\Pi)$ is of at least comparable, if not greater, importance.¹⁵ An I_2 molecular beam was crossed with pulses of polarized light from a laser-pumped tunable dye laser, and the distribution of recoiling I atoms measured with a mass spectrometer as a function of flight time and of recoil angle measured from the electric vector of the light. The observed $B\text{O}^+u(^3\Pi) \leftarrow X\text{O}^+g(^1\Pi)$, and $1u \leftarrow X\text{O}^+g(^1\Pi)$ transitions are clearly separated both by flight time and recoil angle, as shown in Figure 1.

The upper panel shows the results of photolysis in the main I_2 visible continuum at $21\,510 \text{ cm}^{-1}$ with the polarization set so that the detector is at -70° from the electric vector of the light in the laboratory (lab) coordinate system. This corresponds approximately to measurement perpendicular to the electric vector in a centre-of-mass (c.m.) coordinate system whose origin travels with the moving I_2 molecule. To a good first approximation, the c.m. to lab transformation simply rotates the angular distribution by an angle $\Theta = \arcsin c/u$, in which c is the original speed of the I_2 molecule and u is the c.m. speed of the recoiling I atom. The peak is at such short flight times that the dissociation must be to ground-state atoms, as all the photon energy available after breaking the I_2 bond is expressed as translational energy of the atoms. The recoil of the atoms predominantly perpendicular to the electric vector of the light indicates that the transition dipole moment is perpendicular to the internuclear axis (i.e. $\Delta\Omega = \pm 1$, and thus $\Omega = 1$ in the upper state). The only $1u$ states correlating with ground-state atoms are the $A\text{O}^+u(^3\Pi)$ and $1u(^1\Pi)$. The $A\text{O}^+u(^3\Pi)$ should lie lower and almost certainly corresponds, as in the usual assignment, to the weak long-wavelength bands and continuum. That this weak continuum indeed corresponds to a $1u$ state has also been confirmed by photofragment spectroscopy at $14\,405 \text{ cm}^{-1}$. Thus, the peak shown in the
