# WELCOME

Welcome to the 1997 International Symposium on Low Power Electronics and Design. This is the second year of this symposium, which is the result of a merger between the Symposium on Low Power Electronics and the International Symposium on Low Power Design. Like its predecessors, the symposium contains a mix of invited talks and contributed papers. All invited talks will be in plenary sessions, and thus can be heard by all attendees. Most other sessions will consist of two parallel tracks: one focusing on systems and CAD, the other focusing on circuits and technology.

A total of 102 contributed papers were received. This strong response attests to the continuing level of interest in low power design across the international VLSI technical community. Many thanks to the authors who submitted papers, which report significant advances in the domain of low power electronics and design. Even with the parallel sessions, we were able to accept only 42 regular papers. In addition to regular papers presented orally, we have accepted 17 poster papers that will be displayed in two poster sessions scheduled during extended breaks, so that attendees can visit all poster papers of interest to them.

The plenary sessions will be highlighted by invited talks, six in all, including two talks at the keynote session on the first day. There will also be a special talk at the banquet that evening by James Meindl, on the subject of the history of low power electronics, from his perspective of innovative participation in that history over the past several decades.

An evening panel session on the second day will feature the fictional company, Speedy Microsystems, and its contractor team of experts who are trying to design their next-generation multimedia microprocessor, with highly-demanding specs on power and performance. It should be a stimulating event of interest to all attendees.

For the first time, we will offer two half-day tutorials, one on low-voltage design techniques and another on CAD methodologies. These tutorials will present techniques employed currently in industry as well as future trends.

Many thanks to the program committee for doing an excellent job of paper selection and session organization. Thanks also to the panel organizers and panelists for what should prove to be an enlightening and entertaining evening session. We thank Lew Terman for his continuing assistance in preparations for the conference. Finally, we want to thank the ACM SIGDA and the IEEE Circuits and Systems Society for their sponsorship, and the IEEE Solid-State Circuits Society for their technical co-sponsorship and technical support.

We hope you will find the symposium both stimulating and helpful. Please give us your comments and suggestions on any aspects of the conference.

# TABLE OF CONTENTS

## Keynote Session

Chair: Brock Barton

### Low-Power CMOS Design through $V_{TH}$ Control and Low-Swing Circuits

*Takayasu Sakurai, Hiroshi Kawaguchi, Tadahiro Kuroda* .....1

## Session M1

### Digital Circuit Techniques

Chair: Dan Dobberpuhl, Digital Equipment Corp

M1.1	<b>Survey of Low Power Techniques for ROMs</b> <i>Edwin de Angel, Earl E. Swartzlander, Jr.</i> .....7
M1.2	<b>High-Performance, Low-Power Design Techniques for Dynamic to Static Logic Interface</b> <i>June Jiang, Kan Lu, Uming Ko</i> .....12
M1.3	<b>LVDCSL: Low Voltage Differential Current Switch Logic, A Robust Low Power DCSL Family</b> <i>Dinesh Somasekhar, Kaushik Roy</i> .....18

## Session M2

### System Level Power Optimization

Chair: Jason Cong

M2.1	<b>System-Level Power Optimization of Special Purpose Applications: The Beach Solution</b> <i>Luca Benini, Giovanni De Micheli, Enrico Macii, Massimo Poncino, Stefano Quer</i> .....24
M2.2	<b>Formalized Methodology for Data Reuse Exploration in Hierarchical Memory Mappings</b> <i>J. Ph. Diguët, S. Wuytack, F. Catthoor, H. De Man</i> .....30
M2.3	<b>A Low-Power Design Method Using Multiple Supply Voltages</b> <i>Mutsunori Igarashi, Kimiyoshi Usami, Kazutaka Nogami, Fumihiro Minami, Yukio Kawasaki, Takahiro Aoki, Midori Takano, Chiharu Mizuno, Takashi Ishikawa, Masahiro Kanazawa, Shinji Sonoda, Makoto Ichida, Naoyuki Hatanaka</i> .....36

## Invited Talk

Chair: Sayfe Kiaei

### Minimizing Power Dissipation of Cellular Phones

*Sven Mattisson* .....42

## Session M3

### Wireless Communication Circuits

Chair: R.J. van de Plassche

M3.1	<b>A 1V, 5mW, 1.8 GHz Balanced Voltage-Controlled Oscillator with an Integrated Resonator</b> <i>Donald A. Hitko, Theodore L. Tewksbury, Charles G. Sodini</i> .....46
M3.2	<b><math>\Delta</math>-<math>\Sigma</math> Frequency-to-Time Conversion by Triangularly Weighted ZC Counter</b> <i>M. Høvin, S. Kiaei, T. S. Lande</i> .....52

## Session M4

### Register Transfer High-Level Synthesis

Chair: R. Iris Bahar

M4.1	<b>A Symbolic Algorithm for Low-Power Sequential Synthesis</b> <i>Balakrishna Kumthekar, In-Ho Moon, Fabio Somenzi</i> .....56
------	---

<b>M4.2</b>	<b>Low Power High Level Synthesis By Increasing Data Correlation</b> <i>Dongwan Shin, Kiyoungh Cho</i> .....	62
-------------	---	----

## Session P1 Poster Sessions

Chair: Sayfe Kiaei

<b>P1.1</b>	<b>A Programmable Power-Efficient Decimation Filter for Software Radios</b> <i>Emad N. Farag, Ran-Hong Yan, Mohamed I. Elmasry</i> .....	68
<b>P1.2</b>	<b>Techniques for Low Energy Software</b> <i>Huzefa Mehta, Robert Michael Owens, Mary Jane Irwin, Rita Chen, Debashree Ghosh</i> .....	72
<b>P1.3</b>	<b>Low Power Multiplication for FIR Filters</b> <i>Chris J. Nicol, Patrik Larsson</i> .....	76
<b>P1.4</b>	<b>Low-Power H.263 Video CoDec Dedicated to Mobile Computing</b> <i>Morgan H. Miki, Gen Fujita, Takao Onoye, Isao Shirakawa</i> .....	80
<b>P1.5</b>	<b>Scheduling for Power Reduction in a Real-Time System</b> <i>Jason J. Brown, Danny Z. Chen, Garrison W. Greenwood, Xiaobo (Sharon) Hu, Richard W. Taylor</i> .....	84
<b>P1.6</b>	<b>Engineering Change for Power Optimization Using Global Sensitivity and Synthesis Flexibility</b> <i>Premal Buch, Christopher K. Lennard, A. Richard Newton</i> .....	88
<b>P1.7</b>	<b>Synthesis of Low-Power Asynchronous Circuits in a Specified Environment</b> <i>Steven M. Nowick, Michael Theobald</i> .....	92
<b>P1.8</b>	<b>Quasi-Static Energy Recovery Logic and Supply-Clock Generation Circuits</b> <i>Yibin Ye, Kaushik Roy, Georgios I. Stamoulis</i> .....	96
<b>P1.9</b>	<b>A New 4-2 Adder and Booth Selector for Low Power MAC Unit</b> <i>Bum-Sik Kim, Dae-Hyun Chung, Lee-Sup Kim</i> .....	100
<b>P1.10</b>	<b>Enhanced Prediction of Energy Losses During Adiabatic Charging</b> <i>A. Schlaffer, J.A. Nossek</i> .....	104

## Session M5 Analog Circuit Techniques

Chair: Louis Williams

<b>M5.1</b>	<b>Charge-Pump Assisted Low-Power/Low-Voltage CMOS Opamp Design</b> <i>J. Zhou, R.M. Ziazadeh, H. Gao, H.-H Ng, H.-T. Ng, D.J. Allstot</i> .....	108
<b>M5.2</b>	<b>A Low Voltage CMOS Current Source</b> <i>Detlev Schmitt, Terri S. Fiez</i> .....	110
<b>M5.3</b>	<b>New Stability Criteria for the Design of Low-Pass Sigma-Delta Modulators</b> <i>J. A. E. P. van Engelen, R. J. van de Plassche</i> .....	114
<b>M5.4</b>	<b>A Capacitor-Based D/A Converter with Continuous Time Output for Low-Power Applications</b> <i>Lapoe Lynn, Paul Ferguson, Jr.</i> .....	119

## Session M6

### Register Transfer & Architectural Level Power Estimation

Chair: Rob Roy

<b>M6.1</b>	<b>Cycle-Accurate Macro-Models for RT-Level Power Analysis</b> <i>Qinru Qiu, Qing Wu, Massoud Pedram, Chih-Shun Ding</i> .....	125
<b>M6.2</b>	<b>A Method of Redundant Clocking Detection and Power Reduction at RT Level Design</b> <i>Mitsuhisa Ohnishi, Akihisa Yamada, Hiroaki Noda, Takashi Kambe</i> .....	131

<b>M6.3</b>	<b>Power Analysis of a 32-bit RISC Microcontroller Integrated with a 16-bit DSP</b> <i>R. S. Bajwa, N. Schumann, H. Kojima</i> .....	137
<b>M6.4</b>	<b>Analytical Energy Dissipation Models for Low-Power Caches</b> <i>Milind B. Kamble, Kanad Ghose</i> .....	143

### **Banquet Talk**

Chair: Anantha Chandrakasan

<b>History of Low Power Electronics: How It Began and Where It's Headed</b> <i>James D. Meindl</i> .....	149
---	-----

### **Invited Talks**

Chair: Massoud Pedram

<b>Issues and Directions in Low Power Design Tools: An Industrial Perspective</b> <i>Jerry Frenkil</i> .....	152
<b>System-Level Power Estimation and Optimization—Challenges and Perspectives</b> <i>Jan M. Rabaey</i> .....	158

### **Session T1**

#### **Low Power Signal Processing**

Chair: Chuck Traylor

<b>T1.1</b>	<b>Dynamic Algorithm Transformations (DAT) for Low-Power Adaptive Signal Processing</b> <i>Manish Goel, Naresh R. Shanbhag</i> .....	161
<b>T1.2</b>	<b>Low Power Motion Estimation Design Using Adaptive Pixel Truncation</b> <i>Zhong-Li He, Kai-Keung Chan, Chi-Ying Tsui, Ming L. Liou</i> .....	167
<b>T1.3</b>	<b>Low Power Signal Processing Architectures for Network Microsensors</b> <i>Michael J. Dong, K. Geoffrey Yung, William J. Kaiser</i> .....	173

### **Session T2**

#### **Logic-Level Power Estimation**

Chair: Farid Najm

<b>T2.1</b>	<b>K2: An Estimator for Peak Sustainable Power of VLSI Circuits</b> <i>Michael S. Hsiao, Elizabeth M. Rudnick, Janak H. Patel</i> .....	178
<b>T2.2</b>	<b>Switching Activity Estimation Using Limited Depth Reconvergent Path Analysis</b> <i>José C. Costa, José C. Monteiro, Srinivas Devadas</i> .....	184
<b>T2.3</b>	<b>Composite Sequence Compaction for Finite-State Machines Using Block Entropy and High-Order Markov Models</b> <i>Radu Marculescu, Diana Marculescu, Massoud Pedram</i> .....	190

### **Session T3**

#### **Memory Techniques**

Chair: Ingrid Verbauwhede

<b>T3.1</b>	<b>Reducing TLB Power Requirements</b> <i>Toni Juan, Tomas Lang, Juan J. Navarro</i> .....	196

## Abstract

This paper describes some of the circuit level techniques for low-power CMOS designs.  $V_{TH}$  control circuits are necessary for achieving low-threshold voltage in high-speed low-voltage applications. As for the low-swing circuit techniques, applications to a clock system, logic part, and I/O's are discussed.

## 1. Introduction

CMOS power dissipation and delay are given by<sup>[1,2]</sup>

$$\text{Power} = p_i \cdot C_L \cdot V_S \cdot V_{DD} \cdot f_{CLK} + I_0 \cdot 10^{\frac{V_{TH}}{S}} \cdot V_{DD} \quad (1)$$

The first term, in (1) represents dynamic power dissipation due to charging and discharging of the load capacitance, where  $p_i$  is the switching probability,  $C_L$  is the load capacitance,  $V_S$  is the voltage swing of a signal, and  $f_{CLK}$  is the clock frequency. The second term is the subthreshold leak term and  $S$  is typically about 100mV/decade.

Figure 1 shows the plot for power and delay assuming 0.5 $\mu$ m design rule. As seen from the figure, lowering  $V_{DD}$  is effective in decreasing power but delay increases. Fig.1(b) shows equi-delay curves and the delay can be maintained if the  $V_{TH}$  is lowered as  $V_{DD}$  is reduced. Lowering  $V_{TH}$ , however, increases subthreshold leakage. In order to cope with this problem,  $V_{TH}$  control schemes have been proposed which are covered in Section 2.

In most cases,  $V_S$  in (1) is the same as  $V_{DD}$ , but in low-swing circuits  $V_S$  is smaller than  $V_{DD}$ . As seen from Eq.(1), reducing  $V_S$  can be one promising way to decrease power consumption. As for the low-swing circuit techniques, applications to a clock system, logic part, and I/O's are discussed in Section 3, 4, and 5, respectively

## 2. $V_{TH}$ control techniques

To maintain throughput while lowering supply voltage to decrease power consumption, it is effective to lower the threshold voltage of MOSFET's. There are, however, issues associated with low  $V_{TH}$  in low  $V_{DD}$  environments.

First, delay fluctuates intolerably with  $V_{TH}$  fluctuation in low  $V_{DD}$  regime. For example, delay increase by 3 times for  $\Delta V_{TH} = +0.15V$  at  $V_{DD}$  of 1V. The second issue is the subthreshold leakage increase. The leakage increases by 10 times for every  $\Delta V_{TH}$  of - 0.1V. The third problem is the inability for  $I_{DDQ}$  test.  $I_{DDQ}$  test is necessary to screen out LSI's with defects and micro-shorts which develop to a failure in a long run.

In order to cope with these issues,  $V_{TH}$  control techniques have been proposed which are summarized in

TABLE 1. Multi-Threshold  $V_{TH}$  CMOS[3,4], MTCMOS in short, tries to decrease the subthreshold leak in standby mode by inserting high  $V_{TH}$  MOSFET in series to normal circuitry. The high- $V_{TH}$  device is turned off in standby mode and completely cut-off the leakage path. The drawback is the large inserted MOSFET which increases area and delay.

While the MTCMOS can solve only the standby leakage problem, the Variable Threshold CMOS[5-9] (VT CMOS) can solve all the three problems. It dynamically varies  $V_{TH}$  through substrate-bias,  $V_{BB}$ . Typically,  $V_{BB}$  is controlled so as to compensate  $V_{TH}$  fluctuations in the active mode, while in the standby mode and in the  $I_{DDQ}$  testing, deep  $V_{BB}$  is applied to increase  $V_{TH}$  and cut off the subthreshold leakage current. The idea to control the  $V_{BB}$  so as to minimize the subthreshold leakage under the condition that a representative circuit shows sufficient speed was also proposed (Frequency adaptive Threshold CMOS, FTCMOS[10]).

The Elastic  $V_{TH}$  CMOS[11], EVTCMOS in short, controls both  $V_{DD}$  and  $V_{BB}$  such that when  $V_{DD}$  is lowered  $V_{BB}$  becomes that much deeper to raise  $V_{TH}$  and further reduce power dissipation. Note that internal  $V_{DD}$  and  $V_{SS}$  are provided by source-follower n- and p- transistors, respectively, whose gate voltages are controlled. In order to control the internal power supply voltage independent from the power current, the source-follower transistors should operate near the threshold. This requires very large transistors.

In VTCMOS, it has been experimentally evaluated that the number of substrate (well) contacts can be greatly reduced in low voltage environments [7-9]. Using a phase-locked loop and an SRAM in a VTCMOS gate-array [8], the substrate noise influence has been shown to be negligible even with 1/400 of the contact frequency compared with the conventional gate-array. A DCT (Discrete Cosine Transform) macro made with the VTCMOS [7] has also been manufactured with substrate- and well- contacts only at the periphery of the macro and it worked without problems realizing more than one order of magnitude smaller power dissipation than a DCT macro in the conventional CMOS design.

## 3. Low-swing circuit for clock system

The four pie charts in Fig.2 shows power distribution in VLSI's. As seen from the charts, the power distribution of VLSI's differs from product to product. However, it is interesting to note that a clock system and a logic part itself consume almost the same power in various chips, and the clock system consumes 20% to 45% of the total chip power. One of the reasons for this large power consumption of the clock system is that the transition ratio of the clock net is

Permission to make digital/hard copy of all or part of this work for personal or classroom use is granted without fee provided that copies are not made or distributed for profit or commercial advantage, the copyright notice, the title of the publication and its date appear, and notice is given that copying is by permission of ACM, Inc. ©1997 ACM 0-89791-903-3/97/08..\$3.50

one while that of the ordinary logic is about one third on average.

In order to reduce the clock system power, it is effective to reduce a clock voltage swing. Such idea is embodied in the Reduced Clock Swing Flip-Flop (RCSFF)[12]. Figure 3 shows circuit diagrams of the RCSFF. The RCSFF is composed of a current-latch sense amplifier and cross-coupled NAND gates which act as a slave latch. This type of flip-flop was first introduced in 1994[14] and extensively used in a microprocessor design[13]. The sense-amplifying F/F is often used with low-swing circuits because there is no DC leakage path even if the input is not full swing being different from the conventional gates or F/Fs.

The salient feature of the RCSFF is to accept a reduced voltage swing clock. The voltage swing,  $V_{clk}$ , can be as low as 1V. When a clock driver Type A in Fig. 4 is used, power improvement is proportional to  $V_{clk}^1$ , while it is  $V_{clk}^2$  if Type B driver is used. Type A is easy to implement but less efficient. Type B needs either an external  $V_{clk}$  supply or a DC-DC converter.

The issue of the RCSFF is that when a clock is high to  $V_{clk}$ , P1 and P2 do not switch off completely, leaving leak current flowing through either P1 or P2. The power consumption by this leak current turns out to be permissible for some cases (see next section), but further power improvement is possible by reducing the leak current. One way is to apply backgate bias to P1 and P2 and increase the threshold voltage. The other way is to increase the  $V_{TH}$  of P1 and P2 by ion-implant, which needs process modification and is usually prohibitive. When the clock is to be stopped, it should be stopped at  $V_{SS}$ . Then there is no leak current.

#### A. Area & Speed

The area of the RCSFF is about 20% smaller than the conventional F/F as seen from Fig. 5 even when the well for the precharge PMOS is separated.

As for delay, SPICE analysis is carried out assuming typical parameters of a generic 0.5 $\mu$ m double metal CMOS process. The delay depends on  $W_{clk}$  ( $W_{clk}$  is defined in Fig.3). Since delay improvement is saturated at  $W_{clk} = 10\mu$ m, this value of  $W_{clk}$  is used in the area and power estimation. Clock-to-Q delay is improved by a factor of 20% over the conventional F/F even when  $V_{clk} = 2.2V$ , which can be easily realized by a clock driver of the Type A1. Data setup time and hold time in reference to clock are 0.04ns and 0ns, respectively being independent from  $V_{clk}$ , compared to 0.1ns and 0ns for the conventional F/F.

#### B. Power

The power in the Fig.6 includes clock system power per F/F and the power of a F/F itself. The power consumption is reduced to about 1/2~1/3 compared to the conventional F/F depending on the type of the clock driver and  $V_{WELL}$ . In the best case studied here, 63% power reduction is observed. TABLE 2 summarizes typical

performance improvement.

#### C. Application to reduced swing bus

For the RCSFF, the D and  $\bar{D}$  input can also be small voltage swing signals. Using this characteristics, the RCSFF can be used to speed up RC delay of long buses. By placing the RCSFF at the end of a long bus and by sense-amplifying the slowly changing D input, RC delay can be reduced to 1/3 compared to the conventional F/F case (see Fig.7).

Let us consider what amount of power gain is observed when a distributed RC line is driven in full swing<sup>[15]</sup> at one end and switched off when the other terminal becomes  $V_2$ .

$$\frac{V(x,t)}{V_{DD}} = 1 + \frac{2}{\pi} \sum_{k=1}^{\infty} \frac{(-1)^k}{k - \frac{1}{2}} \cos\left\{\left(k - \frac{1}{2}\right)\pi\left(1 - \frac{x}{L}\right)\right\} e^{-\left(k - \frac{1}{2}\right)^2 \pi^2 \frac{t}{RC}}$$

$$Q = \int_0^L C V(x,t) dx = C V_{DD} \left\{ 1 - \frac{2}{\pi} \sum_{k=1}^{\infty} \frac{1}{\left(k - \frac{1}{2}\right)^2 \pi^2} e^{-\left(k - \frac{1}{2}\right)^2 \pi^2 \frac{t}{RC}} \right\}$$

If the energy per cycle,  $E (=QV_{DD})$ , is expressed in terms of the terminal voltage,  $V_2 (=V(L,t))$ ,  $E \approx 0.36 + 0.64V_2$ . This means that about 50% power saving is possible if an RC interconnect is driven when the voltage swing of  $V_2$  is 0.2V<sub>DD</sub>.

#### 4. Low-swing circuit for logic

A pass transistor logic is known to provide a low-power design style. An attempt has been made to further reduce the power-delay product by reducing the signal voltage swing. A Sense-Amplifying Pass-transistor Logic (SAPL) [14] is such a circuit. In the SAPL, a reduced output signal of NMOS pass-transistor logic is amplified by a current latch sense-amplifier to gain speed and save power dissipation as shown in Fig. 9 and Fig.10. The SAPL has been applied to a 1.5ns 20bit carry skip adder in a Discrete Cosine Transform (DCT) macro whose circuit diagram is shown in Fig. 11. 50% speed, 30% area, and 50% power advantage were observed compared with the conventional static CMOS design.

The SAPL is also applied to a 0.9ns 64bit to 32bit double barrel shifter. In this case, 100% speed, 50% area, and 50% power advantage were observed. The MPEG2 decoder LSI which utilizes the DCT and VLD macro with SAPL operates under 0.9V supply voltage.

#### 5. Low-swing circuit for I/O

Application of low-swing circuit to I/O's is also possible. The circuit diagram is shown in Fig.14. The transmitted signal is differential and again is received by a current-latch type sense-amplifier F/F. The two chips are put side by side and bonded directly with minimum capacitance and inductance. The photos of the system are shown in Figs.15 and 16.

At the frequency of 500MHz, the power consumption is 13mW per bonding which includes output and input power (see Fig. 17).

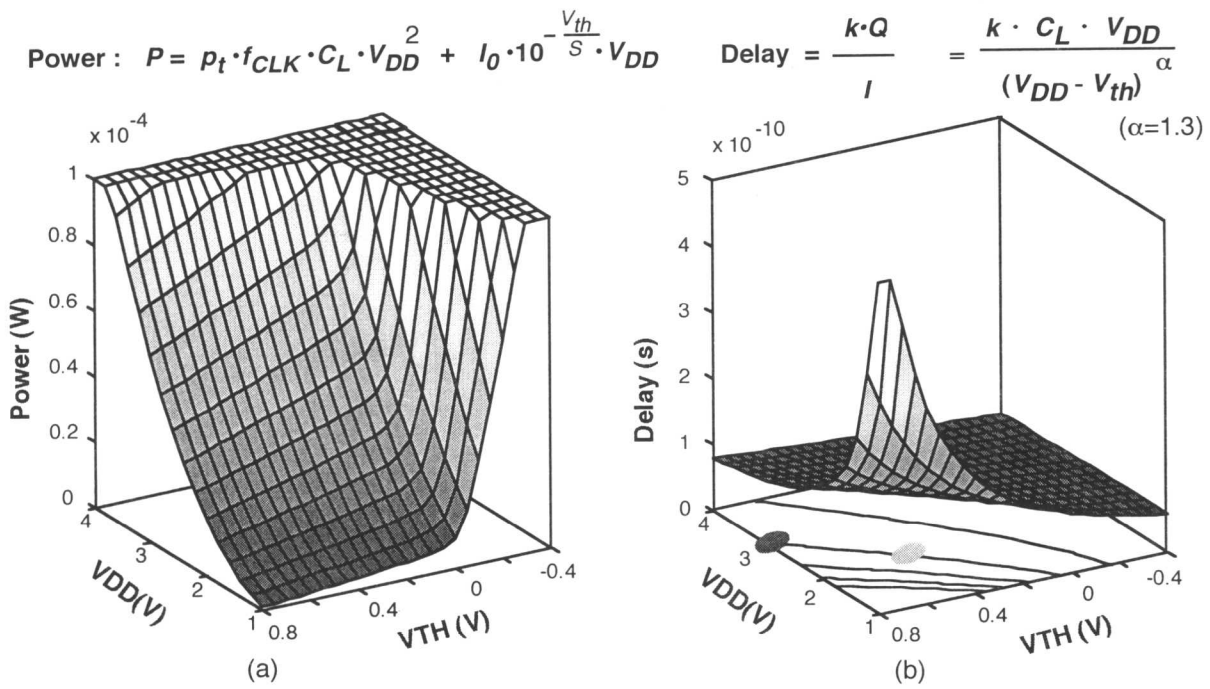

Fig.1 Dependence of (a) power and (b) delay on the supply voltage,  $V_{DD}$  and the threshold voltage,  $V_{TH}$ .

TABLE 1 Comparison of various  $V_{TH}$  control techniques

	MTCMOS	VTMOS	EVTMOS
Scheme	<p>Ref.[ 3,4 ]</p>	<p>Ref.[ 5-9 ]</p>	<p>Ref.[ 11 ]</p>
	$V_{DD}$ on-off	$V_{BB}$ control	$V_{DD}$ & $V_{BB}$ control
Effect	+ $I_{st'by}$ reduction	+ $\Delta V_{th}$ compensation + $I_{st'by}$ reduction + $I_{DDQ}$ test	+ $\Delta V_{th}$ compensation + $I_{st'by}$ reduction + $I_{DDQ}$ test
Penalty	- large serial MOSFET (*) - slower, larger, lower yield - special latch	- triple well (desirable)	- large serial MOSFET - operating near threshold(*)

## Abstract

*This paper presents a survey of low power techniques for Read Only Memories (ROMs). Significant savings in power dissipation are achieved through the use of techniques at the circuit and architecture level. The ROM circuits have been designed in 0.35  $\mu\text{m}$  CMOS technology and simulated using PowerMill.*

## Introduction

With the development of submicron technologies and the increase of complexity on VLSI chips, the market for portable applications, digital signal processors and ASIC implementations has focused significant effort on the design of low power systems [1]. ROMs (Read Only Memories) are an important part of many digital systems (e.g., digital filters, digital signal processors, microprocessors etc). The high area density of ROMs makes these types of circuits very attractive to store fixed information (e.g., coefficients of a digital filter). As new submicron technologies are developed, the fast speeds of these processes allow the implementation of architectures which could not be implemented in the past. Also the increase in the number of metal layers becomes a main instrument to reduce switched capacitance without penalty in the density of the ROM. Significant savings in power are achieved through the implementation of several techniques. The focus of this paper is on techniques at the architecture and transistor levels and their global impact on power dissipation.

The first section of the paper explains traditional ROM designs and the sources of power dissipation. The second part of this paper discusses low power techniques at the architecture level. The next section presents techniques that are applicable at the circuit level. The last section shows results and conclusions.

## 1 Sources of Power Dissipation

Figure 1 shows the traditional architecture of a ROM. The decoder selects among the row lines that run through the ROM core, turning on only one row line at a given time. The column multiplexer and driver select which column is being read and drive the data bus. The control logic generates the internal signals of the ROM (i.e.,

precharge, read etc.). The ROM core is used to store information through the placement of transistors. There are two main types of ROMs: NAND array, where pull down transistors are in series and NOR array where the pull down transistors are in parallel. This paper focuses on ROMs using a NOR array since these structures are faster than NAND arrays and are the most frequently used [2].

Figure 1: ROM Block Diagram

Figure 2: ROM Bitlines

In order to save power, most ROMs precharge during one phase of the clock and evaluate in the other. Table 1 shows the power dissipation in a 2K x 18 ROM designed in 0.6  $\mu\text{m}$  technology at 3.3V and clocked at 10 MHz. As the table shows, the precharge of the bit lines in the ROM core dissipates most of the power. There are two main reasons for this. First, bit lines have large capacitance (drain capacitance of the transistors tied to this line, parallel plate and fringe component to substrate plus the overlap of the row lines and other metal layers). Second, more than 18 bit lines are switched per access; this is due to the word line selecting more bit lines than
