## BIOLOGICAL MEMBRANES

This graduate text, suitable for students of physiology and biophysics, and medical students specializing in neurophysiology and related fields, provides a comprehensive discussion of biological mass transfer and bioelectrical phenomena. Emphasis has been given to the applicability of physics, physical chemistry and mathematics to the quantitative analysis of biological processes, with all the necessary mathematical grounding provided in Chapter 1.

The quantitative analysis is broken into four key stages:

- formulation of a biological/biophysical model,
- derivation of the associated mathematical description of the model,
- solution of the mathematical expression, and
- interpretation of the mathematical solution to a biological explanation.

This book guides the student through these stages, which are central to the understanding of cell membrane functions.

# Foreword

I was delighted when my friend Ove Sten-Knudsen asked if I would write a Foreword to this English translation of his book on biological membranes. I confess that I then had no idea of the immense scope and magisterial quality that I found when I saw the proofs. I wish that such a book had been available in the days when I was concerned with membranes and ion movements: I often had to struggle through the derivation of equations that are here worked through step by step. This will be invaluable not only to students but to the many biologists who work on membranes and use mathematics but are not themselves mathematicians in the full sense of the word. It will also be a major convenience to have the whole background collected in a single volume, instead of being scattered in numerous articles and books.

Another feature that gives me great pleasure is the biographical notes on the authors of classical papers in the field. Whenever one of those great men is mentioned for the first time, there is a footnote telling us his dates, where he worked and his main achievements. This is a welcome contrast to the usual practice of merely giving a name with no indication that it refers to an actual human being.

The book's title hardly does justice to its content: as well as dealing with the properties shared by all cell membranes, it includes very full accounts of the fundamentals of nerve conduction and of synaptic transmission. These were established half a century ago and nowadays they are too easily taken for granted while emphasis is put on the more modern studies of ion channels that followed from them.

This book will be a godsend to all who aim for a quantitative understanding of membrane phenomena.

Sir Andrew Huxley, OM, FRS  
Cambridge  
April 2002

# Preface

I often say that when you can measure what you are speaking about, and express it in numbers, you know something about it; but if you cannot measure it, when you cannot express it in numbers, your knowledge is of a meager and unsatisfactory kind: It may be the beginning of knowledge, but you have scarcely in your thought advanced to the stage of science.

*Lord Kelvin, 1883*

The phenomena of mass transfer and electric activity across biological cell membranes involve a variety of complex processes. To be able to understand and describe these basic mechanisms it is essential to have a thorough insight into the nature of mass transfer by migration, diffusion, and electrodiffusion, and of concepts and fundamental principles of physics and physical chemistry. It is difficult to understand and describe processes in a biological membrane without leaning on the knowledge of mechanisms that operate in simpler systems. In describing transport processes through a cell membrane, we use the concepts of simple passive transport theory. Command of these concepts is the basis on which one performs a quantitative analysis of processes that are observed experimentally.

The purpose of the present book is to give an overall account of diffusion, electrodiffusion, equilibrium potentials, diffusion potentials and membrane potentials, and, in this connection, to take relevant examples from membrane physiology/biophysics to illustrate the use of these tools in a quantitative analysis of the experimental results. It is hoped that the text may be of use to undergraduate studies in general physiology/biophysics and to some postgraduate researchers.

The mathematical background needed to read the book corresponds to the level of a college student graduating in science. These prerequisites for reading the book are presented in **Chapter 1**. They serve to refresh the memory of the reader, making frequent use of cross-reference in the following chapters. In the

following chapters, the mathematical build-up is developed in detail without requiring an additional mathematical course. In this respect the book is self-contained. The presentation of the mathematics is deliberately written in a user-friendly manner, intended for readers who are not professional mathematicians or physicists. Therefore, the mathematical derivations are written out in detail, which may appear unnecessarily detailed to a reader who is skilled in handling mathematics. It is my experience that in this way most readers with no basic training in mathematics can be brought to understand – and later to apply – rather complicated mathematics. On the other hand I do not want to conceal the fact that at places the reader *is* confronted with problems that unavoidably are rather complicated to handle. But the reader will never meet the rather condescending phrase: ‘it is easily seen that . . .’.

The theory of mass transfer by diffusion, migration, and by the superposition of these processes, is developed in **Chapter 2**. The chapter starts by introducing principles of migration flux and diffusion flux that define the associated parameters mobility and diffusion coefficient. This leads to the law of mass conservation (the diffusion equation). The exposition is based upon macroscopic considerations. Later these processes are reconsidered from the microscopic point of view of *Brownian motion* and *Boltzmann statistics*. I regard the introduction of these complementary aspects to be particularly useful to understand mass transfer across cell membranes. To solve the time-dependent diffusion equation no use is made of integral transforms, a mathematical technique that is beyond the scope of this book. Ludwig Boltzmann used an inspired transformation that by simple allowed him means to find a particular solution of the diffusion equation in terms of the Error function. The presentation in this book succeeded in using adaptations of this solution to solve both the new diffusion problems in **Chapter 2** and to handle problems in the remaining chapters.

**Chapter 3** deals with the theory of transport of ions in aqueous solutions, as well as the origin of electric potential differences across cell membranes, i.e. membrane potentials. The basis for this is the theory of *electrodifffusion*: diffusion superimposed upon migration of ions with an electric field as driving force. The chapter starts by introducing the necessary concepts: electric potential and field, electric conductance of a single ion and of a mixture of ions. The Nernst–Planck equations, the equations of electrodiffusion most frequently occurring in electrophysiology, follow as a natural sequel of the general transport equation in Chapter 2. The condition of *electronutrality* is assumed to hold almost throughout. The *equilibrium potential* across a membrane is introduced by applying the Nernst–Planck equation to the transport across an ion selective permeable membrane. The Donnan system is treated partly by making use of a thermodynamic argument and partly by using the Poisson–Boltzmann equation

to determine the potential and concentration profiles. The treatment of the *diffusion potential* begins by considering the concentration differences of a single salt. This is followed by the descriptions of the general diffusion regimes of Planck and by Henderson which both relate to a membrane that is separated by mixtures of electrolytes of different composition. Membrane potentials in living biological cells will be described as complex diffusion potentials. Of common interest are three types of membrane whose properties are described in detail: (1) the anion/cation selective permeable membrane; (2) the constant field membrane (Goldman equation), and (3) the mosaic membrane, each type having its own merits. The chapter ends by comparing the membrane potentials obtained in experiments on a living single frog-muscle cell with those predicted from theory.

Most readers of this book are assumed to be biologists seeking an in-depth understanding of biological transport and bioelectrical phenomena. **Chapter 4** comprises a bridge between the theoretical treatment and some fundamental biological experiments performed in nerve (and muscle) fibre. Thus the chapter is essential for demonstrating the applicability of physics and physical chemistry to biology. Furthermore, it contains analyses not been treated in the previous chapters (e.g. cable analysis). The chapter starts by summarizing the basic properties of nerve excitability and impulse transmission. The emphasis is the meticulously planned and epoch-making work on the axon of the squid (*Loligo*) by A.L. Hodgkin & A.F. Huxley, with participation of B. Katz and R.D. Keynes. The experimental results were interpreted and followed by a quantitative analysis accounting for the origin of the action potential in the giant nerve of the squid. The lessons to be learned from this work extend far beyond its relation to nerve activity.

**Chapter 5** presents the important investigations of Katz and co-workers on the processes involved in the neuromuscular transmission, where statistical arguments were used to account for their observations.

It should be emphasized that the aims of **Chapter 4** and **Chapter 5** are not to provide an up to date review of the field. The examples chosen only serve the didactic intentions of this book.

The basis of the present book is a similar text published in Danish in 1995\* aimed at students of general physiology, biophysics and postgraduate researchers in neuromedicine. The present book is the result of many revisions and it has been supplemented with new sections.

I wish to thank my colleagues professor Rodney Cotterill, Dr phil & scient, Professor Erik Hviid Larsen, Dr scient, and Professor Ulrik V. Lassen, Dr med.,

\* O. Sten-Knudsen (1995): *Stoftransport, membranpotentialer af elektriske impulser over biologiske membraner*. Akademisk Forlag, København.

for their encouragement to write the manuscript and for their help and advice in connection with its submission for publication; likewise Senior Lecturer Jørgen Warberg, Dr med., Head of Department of Medical Physiology for hospitality and assistance, and to Senior Lecturer Per Hedegaard, Lic. scient., and Mr Peter Busk Laursen, UNI-C, for instruction in handling some special typesetting problems. Ms. Nina Sten-Knudsen has given great help in making the line drawings. My particular thanks goes to Senior Researcher Else Marie Bartels, Ph.D., D.Sc., for giving me the inestimable help in reading the proofs of the book and in the completion of the index and the list of references.

I am most grateful to the Press Syndicate of The Cambridge University Press and their staff for publishing the book, in particular Dr Shana Coates, Editor (Biological Sciences), for in her friendly manner of directing the manuscript (and its author) from beginning to completion, and Mrs Beverly Lawrence for her expert copy-editing of a difficult manuscript and for excellent communication via e-mail, and also to Ms Carol Miller, production controller.

My thanks are also due to the authors referred to in the legends for kindly allowing me to copy figures from their papers and for confirming their permissions in writing, as well as to editors of the journals: *J. Physiol.*, *J. gen. Physiol.*, *Biophys. J.*, *Proc. R. Soc. Lond.*, *Progr. Biophys.*, *Nature*, *J. Neurophysiol.*, *Amer. J. Physiol.*, *Amer. J. Med.*, *Arch. Sci. Physiol.* and to Liverpool University Press, McGraw-Hill Education, Charles C. Thomas Publisher and University of California Press.

The Carlsberg Foundation has kindly supported the work by grants to providing the author with the adequate EDP equipment and to cover expenses related to the publication of the book.

Finally, it gave me great pleasure that Sir Andrew Huxley, OM, FRS, kindly agreed to write the Foreword to the book. I also greatly appreciated the concomitant constructive comments to the text.

<i>Foreword</i>	page xix
<i>Preface</i>	xxi
1 Mathematical prelude	1
1.1 Introduction	1
1.2 Basic concepts of differential calculus	2
1.2.1 Limits	2
1.2.2 Functions	2
1.2.3 The derivative	3
1.2.3.1 A few derived functions	6
1.2.4 Approximate value of the increment $\Delta y$	6
1.2.5 Differential	8
1.2.5.1 The chain rule	9
1.2.5.2 The derivative of the inverse function	10
1.3 Basic concepts of integral calculus	11
1.3.1 Definite and indefinite integral	12
1.3.2 The fundamental law	14
1.3.3 Evaluation of a definite integral	15
1.3.4 The mean value theorem	17
1.4 The natural logarithm	18
1.4.1 Definition of the natural logarithm	18
1.4.2 Elementary properties of the logarithm	19
1.4.2.1 Logarithm of a product	20
1.4.2.2 Logarithm of a quotient	21
1.4.2.3 Logarithm of an exponential	22
1.5 The exponential function	22
1.5.1 Definition of the exponential function	22
1.5.2 Derivative and integral	25

1.6	Taylor's theorem	26
1.6.1	Taylor and Maclaurin series	26
1.6.1.1	Expansion of a polynomial	26
1.6.1.2	Expansion of an arbitrary function	27
1.6.1.3	The binomial series	28
1.6.2	Series of the logarithmic and exponential functions	30
1.6.2.1	The logarithm	30
1.6.2.2	The exponential function	31
1.6.3	Approximate expressions of functions	32
1.6.4	Evaluation of an undetermined expression 0/0	33
1.7	Basic techniques of integration	34
1.7.1	The method of substitution	34
1.7.2	Partial integration	36
1.8	Functions of several variables	38
1.8.1	Geometrical representation	40
1.8.2	Partial derivatives	40
1.8.3	Total differential	43
1.8.4	The chain rule once more	45
1.9	Some ordinary differential equations	49
1.9.1	Four first-order differential equations	50
1.9.1.1	The equation $y' + \alpha y = 0$	51
1.9.1.2	The equation $y' + \alpha y = K$	52
1.9.1.3	The equation $y' + \alpha y = Q(x)$	53
1.9.1.4	The equation $y' + P(x)y = Q(x)$	53
1.9.2	Two second-order differential equations	55
1.9.2.1	The equation $y'' + \kappa^2 y = 0$	55
1.9.2.2	The equation $y'' - \kappa^2 y = 0$	56
1.10	A note on partial differential equations	57
2	Migration and diffusion	62
2.1	Introduction	62
2.2	Flux	65
2.3	Types of passive transport	65
2.4	Migration	66
2.4.1	Friction coefficient and mobility	66
2.4.2	Migration flux	68
2.5	Diffusion	70
2.5.1	Phenomenological description	70
2.5.2	Diffusion flux (Fick's law)	73
2.5.2.1	The diffusion coefficient	74
2.5.2.2	A simple application of Fick's law	75

2.5.3	The diffusion equation	76
2.5.3.1	Diffusion with mass conservation	77
2.5.3.2	Diffusion with concurrent mass production	79
2.5.3.3	Classification of diffusion processes	79
2.5.4	Stationary diffusion processes	80
2.5.4.1	One-dimensional diffusion	81
(i)	Diffusion through a plate	81
(ii)	Diffusion through two adjoining, different media	84
(iii)	Unstirred layers	87
(iv)	Plate covered on one side by a membrane of permeability $P$	89
(v)	Diffusion with mass consumption	91
2.5.4.2	Diffusion in a cylinder with radial symmetry	99
(i)	The diffusion equation	100
(ii)	Diffusion through a cylindrical shell	103
(iii)	Diffusion in a cylinder with mass consumption	105
(iv)	Diffusion from a cylinder into the surrounding medium with mass consumption (Krogh's cylinder)	108
2.5.4.3	Diffusion with radial symmetry in a sphere	111
(i)	The diffusion equation	111
(ii)	Diffusion through a spherical shell	114
(iii)	Sphere covered by a thin membrane, mass consumption in the interior	115
2.5.5	Time-dependent diffusion processes	117
2.5.5.1	An extended initial distribution (Boltzmann's trick)	117
2.5.5.2	Diffusion from a region with constant concentration	123
2.5.5.3	Duhamel's integral	124
2.5.5.4	An instantaneous surface distribution	127
2.5.5.5	Green's function	130
(i)	A varying initial distribution in space	130
(ii)	Initial uniform distribution in the infinite half-space	133
(iii)	The effect of an impermeable barrier	133
