# **SOLID MECHANICS**

# Foreword

I HAVE great pleasure in writing this foreword to the textbook on “Solid Mechanics” by Dr. S. M. A. Kazimi, Assistant Professor at the IIT, Delhi.

It is a new effort to present the subject. General concepts precede the engineering theory of strength of materials. It will help students to gain a more than superficial knowledge of the subject. Experimental aspects have been interwoven into the text. The numerous illustrative examples enhance the value of the text and make it easy for the beginner to thoroughly grasp the presentation of the theory.

The young author is to be commended on his efforts in authoring such a comprehensive textbook. Teachers as well as students will find it of considerable interest in presenting and learning solid mechanics.

G. S. RAMASWAMY

# Preface

THIS textbook is an outgrowth of my class lectures, delivered to various groups of students, at the third and fourth year level, in my seven years at the IIT, Delhi. Most of the topics presented here were discussed in the first course on Solid Mechanics, which was given as a core course to various disciplines like civil engineering, mechanical engineering and textile engineering. Free discussions with the outgoing students and informal opinion polls provided the feedback and have helped to improve the book. In its present form there is obviously more material than can be covered in a 6-hour, 4-credit course, and enough topics can be skipped over in the first course, to form the basis of a second course at the fourth or fifth year level.

A unified approach has been adopted and wherever possible a synthesis of the strength of material and theory of elasticity has been affected. No attempt has been made to classify the subject matter into less advanced and more advanced topics. It is left to the teacher to design a suitable course according to his specific interest and the level of the students. A careful study of the table of contents should make his task less difficult.

M.K.S. units have been adopted in this edition to make the book immediately useful to students. Provision for future conversion to SI units is kept for the next edition, and a detailed note on SI units has been added as appendix I, for ready reference.

I wish to thank my students who have helped to improve the book in some way; either by an awkward question or a brilliant remark. My thanks are also to my colleagues and seniors at the IIT, Delhi, particularly Prof. B. Karunes and Prof. K. Seetharamulu for their comments and discussions. I am grateful to Prof. G. S. Ramaswamy, Director of the Structural Engineering Research Centre, Madras, for looking through the manuscript and writing a precise foreword. Finally I thank the National Book Trust for

## INTRODUCTORY 1-9

1. Mechanics of Solids—Definition and Scope 1
2. Strength of Materials versus Theory of Elasticity 2
3. Structural Analysis and Design Scheme 3
4. Types of Forces 3
5. Statical and Kinematical Indeterminacy 6
6. Henderson's Theory of Statical Indeterminacy 8

## *PART—A (General Analysis)*

### 1. DEFORMABLE BODIES (BASIC CONCEPTS; MECHANICAL PROPERTIES) 13-37

*Notation* 13

- 1.1 Macroscopic Properties and Phenomenological Approach 14
- 1.2 Isotropy, Homogeneity and Continuity 14
- 1.3 Mechanical Properties and Tension Test 15
- 1.4 Elasticity, Anelasticity and Work-Hardening 17
- 1.5 Plasticity, Creep and Relaxation 19
- 1.6 Visco-elasticity, Elastic, Plastic and Viscous Models 23
- 1.7 Fatigue and Hysteresis 27
  - 1.7.1 Hysteresis 27

1.7.2	Fatigue	27
(a)	Testing Procedure	29
(b)	Plotting of the Data—The Wöhler Curve	30
(c)	Effect of Mean Stress—The Soderberg Diagram	32
(d)	Effect of Stress Concentration—The Sensitivity Factor	33
(e)	Effect of Surface Finish	33
(f)	Effect of Size—The Size Effect Factor	34
(g)	Physical Interpretation	34
1.8	The Bauschinger Effect	35
2.	ANALYSIS OF STRESSES (EQUILIBRIUM)	38–74
<i>Notation</i>		38
2.1	Definition of Stresses, Types of Stress	39
2.1.1	Internal Forces and Stress	39
2.1.2	Types of Stress	41
2.1.3	Direct and Shear Stresses	41
2.2	Principal Stresses and Principal Planes	41
2.3	Notation of Stress, Sign Conventions	42
2.4	Symmetry of the Stress Tensor	45
2.5	Spherical and Deviatorial Stress Tensors	45
2.6	Equation of Equilibrium	46
2.7	Stresses on Inclined Planes, Transformation of Stresses	50
2.7.1	Stresses at a Point	50
2.7.2	Direction Cosines	50
2.7.3	Equilibrium of the Elementary Tetrahedron	51
2.7.4	Tensor Notation for the Transformation Equations	52
2.8	Particular Applications of the Transformation Equations	55
2.8.1	Octohedral Shear Stress	56
2.8.2	Invariants of Stress Tensor	57
2.8.3	Lame's Stress Ellipsoid	58
2.9	Cauchy's Stress Quadratic	60
2.10	Analysis of Stresses in Two-Dimensions—Plane Stress	62
2.10.1	Introduction	62
2.10.2	Transformation Formulae	62
2.10.3	Principal Stresses	63
2.10.4	Maximum Shear Stress	64
2.11	Graphical Representation of Stresses—Mohr's Circle	64
2.11.1	Introduction	64
2.11.2	Sign Convention	65
2.11.3	Construction of Mohr's Circle	65
2.12	Mohr's Circle for the General State of Stress	71
3.	ANALYSIS OF STRAINS (COMPATIBILITY)	75–105
<i>Notation</i>		75
3.1	Types of Strain, Strain-Displacement Relation	76

3.1.1	Types of Strain	76
3.1.2	Strains and Displacements, Definition of Strain	77
3.2	Strains at a Point	79
3.2.1	Components of Strain Tensor	79
3.2.2	Geometrical Interpretation of Shear Strains and Body Rotation Terms	81
3.3	Properties of Strain Tensor	84
3.3.1	Spherical and Deviatorial Strain Tensor	84
3.3.2	Invariants of Strain Tensor	84
3.3.3	Other Properties	84
3.4	Small Strains and Linear Elasticity	85
3.5	Rotation of Axes, Transformation Equations for Strains	86
3.6	Graphical Representation, Strain Rosettes	91
3.6.1	Types of Strain Rosettes	92
3.6.2	Rosette Analysis	92
3.6.3	Graphical Solution—Murphy's Construction	92
3.7	Compatibility—Concept, Need, and Physical Significance	96
3.8	St. Venant's Equations of Compatibility	97
3.9	Two-Dimensional Cases—Plane Stress and Plane Strain	99
4.	STRESS-STRAIN RELATIONS	106–133
<i>Notation</i> 106		
4.1	Introduction	107
4.2	Generalised Hook's Law and Number of Constants	108
4.3	Bulk Modulus and Lamé's Constants	110
4.4	Formulation of Problems in Elasticity	116
4.4.1	Displacement Formulation or Navier's Equations	116
4.4.2	Stress Formulation, Beltrami-Michell Equations of Compatibility	117
4.5	Plastic Deformations—Yield Criteria and Theories of Failure	119
4.5.1	Yield Criteria	119
4.5.2	Old Theories	119
4.5.3	Modern Theories for Yielding of Ductile Materials	120
4.6	The Yield Conditions of Tresca and Von-Mises	120
4.6.1	Maximum Shear Stress Criterion or Tresca Condition	120
4.6.2	Octohedral Shear Stress Criterion or Von-Mises Condition	120
4.7	Heigh-Westergaard's Stress Space and Yield Surfaces	122
4.8	Plastic Stress-Strain Relations	125
4.8.1	St. Venant's Equations for Plastic Flow	125
4.9	Saint Venant's Principle, Principle of Superposition, and Uniqueness Theorem	127
4.9.1	St. Venant's Principle	127
4.9.2	Principle of Superposition	129
4.9.3	Uniqueness Theorem	130

## *PART—B (Particular Applications)*

5. UNIAXIAL DEFORMATIONS 137-166
  - 5.1 Introduction, Types of Stress Systems Considered 137
  - 5.2 Uniaxial Tension or Compression 138
    - 5.2.1 Bars of Variable Cross-section, or Variable Force in the Direction of Length 140
    - 5.2.2 Compound Bars 143
    - 5.2.3 Prestressed Concrete Tie Bars 147
    - 5.2.4 Temperature Stress and Thermostat Controls 150
    - 5.2.5 Thermostats and Bimetallic Strips 152
    - 5.2.6 Strain Energy in Tension or Compression Resilience 154
  - 5.3 Shearing Stresses and Rivet Design 156
    - 5.3.1 Modes of Failure and Types of a Rivetted Joint 157
    - 5.3.2 Design of Rivets and Efficiency Considerations for a Joint 160
  - 5.4 Pin-jointed Frame Works 161
6. TORSION; INCLUDING NON-CIRCULAR SECTIONS 167-224
  - 6.1 Introduction and History 167
  - 6.2 Analysis of Circular Sections—The Torsion Equation 168
    - 6.2.1 Basic Assumptions 168
    - 6.2.2 The Torsion Equation 169
  - 6.3 Derivation of the Torsion Equation by Exact Methods 171
  - 6.4 Warping of Non-Circular Sections—St. Venant's Method 173
    - 6.4.1 Explanation of the Phenomenon 173
    - 6.4.2 St. Venant's Formulation for General Torsion 173
  - 6.5 Prandtl's Solution using Stress Functions 176
  - 6.6 Membrane Analogy 180
    - 6.6.1 General Theory 180
    - 6.6.2 Analogy of Stresses and Deformations 180
    - 6.6.3 Experimental Set-up 181
    - 6.6.4 General Conclusions 182
    - 6.6.5 Some Applications 183
  - 6.7 Torsion of Thin Hollow Sections 183
  - 6.8 Further Details of Circular Shafts 187
    - 6.8.1 Solid and Hollow Shafts 188
    - 6.8.2 Buckling of Very Thin Hollow Tubes 195
    - 6.8.3 Simple and Compound Shafts 196
    - 6.8.4 Horse Power Transmitted by a Circular Shaft 199
    - 6.8.5 Strain Energy in Torsion 201
    - 6.8.6 Closed Coil Helical Springs 203
      - A. General Definitions 203
      - B. Types of Helical Springs 203
      - C. Stresses and Deflections in Closed Coiled Helical Springs 204
      - D. Energy Stored in Closed Coiled Springs 207
    - 6.8.7 Key-Ways and Stress Concentration 209

- 6.9 Engineer's Approach to Non-Circular Sections—Use of Tables and Formulae 210
  - 6.9.1 Square and Rectangular Sections (Solid) 211
  - 6.9.2 Thin Open Sections and Rolled Structural Shapes 211
  - 6.9.3 Formulae for Other Sections 213
- 6.10 Elasto-plastic Torsion of Circular Shafts 218
- 7. BEAMS AND BENDING 225–321
  - 7.1 Bending Moment and Shear Force Diagrams 226–244
    - 7.1.1 Definitions of B.M., S.F. and Sign Conventions 226
    - 7.1.2 Types of Beams and Supports 229
    - 7.1.3 Relation Between B.M., S.F. and Loading 230
    - 7.1.4 Procedure for Drawing the B.M. and S.F. Diagrams 232
    - 7.1.5 Singularity Functions and Their Uses 238
  - 7.2 Geometrical Characteristics of Cross-Sections of a Beam 244–251
    - 7.2.1 Static Moments of a Section (1st Moment of Area) 245
    - 7.2.2 Moment of Inertia (2nd Moment of Area) 247
      - Rule of Parallel Axes 247
      - Rule of Perpendicular Axes 248
    - 7.2.3 Polar Moment of Inertia 248
    - 7.2.4 Principal Axes and Principal Moments of Inertia 248
  - 7.3 Stresses Due to Bending 251–275
    - 7.3.1 Introduction and History 251
    - 7.3.2 Assumptions in the Technical Theory of Bending 252
      - The Bending Equation* 252
    - 7.3.3 Composite Beams and Built-up Sections 259
    - 7.3.4 Unsymmetrical or Skew Bending 265
    - 7.3.5 Elasto-plastic Bending of Beams 267
      - Plastic Section Modulus* 268
      - Shape Factor* 269
    - 7.3.6 Beams of Large Curvature 272
  - 7.4 Stresses due to Shear 275–290
    - 7.4.1 Examples of Shear Stresses in Beams—Horizontal and Vertical Shear 276
    - 7.4.2 The Shear Formula from Equations of Equilibrium 277
    - 7.4.3 The Shear Formula from Static Equilibrium 278
    - 7.4.4 The Shear Centre and Its Uses 286
    - 7.4.5 Approximate Nature of Shear Stress Formulae 289
  - 7.5 Deflection of Beams 290–310
    - 7.5.1 The Elastic Curve and Its Equation 290
    - 7.5.2 Direct Integration Methods 292
    - 7.5.3 The Moment-Area Method 298
    - 7.5.4 Deflection Due to Shear 305–314
  - 7.6 Design of Beams 310
    - 7.6.1 Modes of Failure of a Beam 310
    - 7.6.2 Steps for Design of Beams 311
    - 7.6.3 I-Beams and Channels, Use of Steel Tables 311
    - 7.6.4 Built up Sections and Plate Girders 312
  - 7.7 Conclusion 314
- 8. STABILITY OF EQUILIBRIUM—COLUMNS 322–355
  - 8.1 Introduction and History 322

8.2	Stable and Unstable Equilibrium	323
8.2.1	Types of Static Equilibrium	323
8.2.2	Equilibrium of Mechanical System	323
8.2.3	Equilibrium of Elastic Systems, Elastic Unstability	325
8.2.4	Examples of Elastic Instability	335
8.3	Stability of a Long Column—Euler's Formula	326
8.4	End Conditions and Theoretical Solutions	328
8.5	End Conditions and Effective Length Factors	333
8.6	General Comments on Euler's Formula—Limitations	334
8.7	Columns with Eccentric Loading—The Secant Formula	337
8.8	Modifications of the Secant Formula and Its Adaption by I.S. 800—1962	339
8.9	Practical (Emperical and Semi-Emperical) Design Formulae	341
8.9.1	The Rankine-Gordon Formula	342
8.9.2	The Parabolic Formula	344
8.9.3	The Straight Line Formula	344
8.9.4	Emperical Formulae for Other Materials	345
8.10	Design of Columns	346
8.10.1	Steps for Design	346

# Introductory

## 0.1 Mechanics of Solids—Definition and Scope

The term ‘Solid Mechanics’ is comparatively new and may not have been known as such in the first quarter of the present century. However, most of the topics covered under this general heading were known to us earlier, and were covered under various subjects like strength of materials, mechanics of materials, structural mechanics, theory of elasticity, theory of plasticity, visco-elasticity, etc. Thus, the present trend towards recognizing Solid Mechanics as a distinct field, is mainly an organizational effort, whereby we rearrange the existing knowledge in a systematic form and try to fill in the gaps, if any, in this overall pattern. Under the new concept, the field of solid mechanics covers the study of mechanical properties of engineering materials and the behaviour of structures made thereof, with the following objects in view :

- (1) To gain a clear insight into the actual phenomena.
- (2) To find the optimum number of simplifying assumptions.
- (3) To bring the calculations to simple numerical results.

The types of problems to be tackled are many and varied. However, in general, we are required to design a machine part or structural element so that it has enough strength, stiffness and stability and is economical in weight and overall cost. To gain this design object, we first analyse the structure to find the forces and stresses at various points. Then we select a suitable material of known deformation behaviour to withstand these loads without too much deformation, and check for stability. In fact, all these operations are interlinked and may have to be done side by side.

It may be noted that the study of solid mechanics is essential for many

## 2 Introductory

branches of engineering like civil, mechanical, aeronautical, chemical, agricultural and textile engineering, and its applications are found in almost every branch of engineering. Thus, it has an inter-disciplinary character and may be studied as a general course at the undergraduate level. However, at higher levels, it is subdivided into various specialized branches, like, strength of materials, theory of elasticity, theory of plasticity, visco-elasticity, visco-plasticity, thermo-elasticity, fracture mechanics, etc. and may be studied at post-graduate to post-doctorate level. In the present book, we shall confine ourselves to the basic undergraduate course that is useful to all the branches of engineering and which can be grasped with a basic knowledge of statics and mechanics.

### 0.2 Strength of Materials and Theory of Elasticity

Both these branches of solid mechanics are very old and have developed, almost, side by side. However, a clear distinction was made earlier between the two, and the pioneers of strength of materials were generally practising engineers and experimentallists while those of elasticity were physicists and mathematicians. In fact, for quite some time mathematical theory of elasticity developed as a branch of applied mathematics, and engineers' interest in it is of a comparatively recent origin.

The types of problems tackled by both are similar but the main difference lies in the approach. Under strength of material, we deal with a particular problem on an ad-hoc basis and find particular solution after making many simplifying assumptions. The approach is generally very simple and the emphasis is on finding a practical solution to the particular problem, rather than on understanding the general phenomenon. On the other hand, we try to formulate the problem in most general terms under the theory of elasticity and obtain a general solution, if possible. Obviously, we have to study the problem in greater depth, but the solutions are not easy in most of the cases and a deeper knowledge of mathematics is necessary. Quite often, the problems solved are not of a practical nature and highly idealised loading and boundary conditions are assumed to obtain a solution. This may be a reason why engineers did not take enough interest in it earlier.

In the present treatment, a happy compromise is reached between these two conflicting demands. As the exposition of the problems, specially the state of stress and strain at every point of a body, is definitely superior under theory of elasticity, we adopt this approach in the first part of the book, under General Analysis. This helps us to understand the problem in greater depth and the implications of various simplifying assumptions, necessary under the strength of material approach. Later on, in the second part, we try to solve practical engineering problems which obviously require a lot of simplifying assumptions. However, as we have already studied the exact theories earlier, the truth is never hidden from us, under

a mass of assumptions and approximations. This helps to develop a clear insight into the problem coupled with a knack for bringing the problem to simple algebraic results by cutting down the unnecessary details. This is the real aim of a design engineer.

### 0.3 Structural Analysis and Design Scheme

Once the general theories of stress and strain (Part I) are learnt and their particular application (Part II) understood, the next step is the design and analysis of a real structure. A mechanical or structural system generally has a large number of components and we have to focus our attention on the machine part or structural element. Other components may be replaced by simple forces or restraints as the case may be. As an example, suppose we have to design a lift system. It consists of a number of parts and let us suppose that we are interested only in the design of ropes. Hence we may conveniently replace the lift cage by a rigid body of known mass and completely disregard its deformation properties. However, if we have to design the lift cage, we have to consider its structural properties, though now, the cables can be replaced by simple forces of known magnitude. These 'isolation' techniques are an essential part of a complete design scheme, and have to be carefully adopted. All this is schematically shown in Fig. 1 (a), (b) and (c).

### 0.4 Types of Forces

All the forces to be encountered by a deformable body (or rigid body for that purpose) may be studied under two systems of classification, i.e. (a) External and internal forces and (b) Surface and body forces. The forces acting on the extremities or exposed surface of a body are known as external forces, whereas those acting inside the body between the grains or molecules are known as internal forces. External forces are sometimes known as boundary forces as well.

The distinction between surface and body forces is not so easy. Sufficient to say that surface forces are acting on an area or surface, whether external or internal. Some examples could be, external loads, contact forces (produced by one body pressing against another) or forces produced by thermal expansion or contraction. Body forces are always acting on every grain of a body and are proportional to volume. Thus gravity force, inertia force and magnetic force are body forces. These are produced by a force field, in general, and could be constant or varying from point to point (vide example 1).

It is possible that a body force on one body may produce a surface force on another body or the exposed boundary of the same body. Suppose a piece of mild steel is resting on a wooden table and a strong magnet is placed below it, to create a strong magnetic field. The magnetic field

**Fig. 0.1** Design scheme for a lift rope and cage  
 a. Lift system  
 b. Design scheme for lift rope  
 c. Design scheme for lift cage (rigid frame)

will produce a body force distribution on the steel, but as far as the wooden table is concerned, it will experience only a surface force at the surface of contact, equal to the total magnetic pull. Further, according to Newton's third law, the piece of steel will also experience an equal and opposite surface force at the surface of contact.

#### Example 1

Fig. 2(a) shows a solid of cubical shape,  $10 \times 5 \times 8$  meters in size. If the density is uniformly increasing from  $2000 \text{ kg/m}^3$  at the bottom face to  $4000 \text{ kg/m}^3$  at the top face, find the intensity of the body force field, and the total body force, under a field of  $4.9 \mathbf{i} + 9.8 \mathbf{j} \text{ m/sec}^2$ .

#### Solution

If we assume the origin at the bottom surface of the solid, the equation for density will be,  $\rho = 2000 (1 + 0.125 y) \text{ kg/m}^3$  and field  $B = 4.9 \mathbf{i} + 9.8 \mathbf{j} \text{ m/sec}^2$ .
