1. Introduction

Poly(vinyl chloride), PVC, a polymer prepared from vinyl chloride monomer (VCM),

where $n = 700 - 1500$, holds a unique position amongst all the polymers produced today. It is relatively inexpensive and is used in such a wide range of applications that its versatility is almost unlimited. However, if it were discovered today it would probably be shelved as a somewhat intractable and thermally unstable material. How can this apparent contradiction be explained?

The uniqueness of PVC can be considered under three headings: morphology, versatility, and molecular structure.

1.1. Morphology

As made, PVC is particulate in nature and comes in two main sizes depending on the process used. Suspension and mass polymerizations give grains (particles) of $100 - 180 \mu\text{m}$ in diameter, whereas the emulsion process affords a latex of particle size $0.1 - 3.0 \mu\text{m}$. The latter is dried to yield friable grain-like structures of $5 - 50 \mu\text{m}$.

Because of this unique particulate structure the most frequently used word in the vocabulary
