VOLUME I

## Volume II

### Subsection C. The Beta Trefoil Cytokines and Proinflammatory Signaling Receptors

- 27 Interleukin-1 Family [IL-1F1, F2]  
*Charles A. Dinarello*
- 28 Interleukin-1 receptor antagonist [IL-1F3]  
*William P. Arend and Christopher H. Evans*
- 29 Interleukin-18 [IL-1F4]  
*Haruki Okamura, Michael T. Lotze, Hiroko Tsutsui, Shin-ichiro Kashiwamura, Haruyasu Ueda, Tomohiro Yoshimoto and Kenji Nakanishi*
- 30 Interleukin-1 Family [F5 to F10]  
*Sanjay Kumar*
- 31 The fibroblast growth factors  
*Barbara Ensoli, Cecilia Sgadari, Giovanni Barillari and Paolo Monini*
- 32 Hepatocyte growth factor and its receptor, MET  
*Wendy M. Mars, Youhua Liu and Satdarshan P. Singh Monga*
- 33 Toll-like receptors  
*Bruce Beutler*

### Subsection D. The TNF Family, Receptors, and Related Molecules

- 34 Lymphotoxins  
*Steve W. Granger and Carl F. Ware*
- 35 Tumor necrosis factor  
*Haichao Wang, Christopher J. Czura and Kevin J. Tracey*
- 36 TRAIL/Apo2L  
*David H. Lynch and Avi Ashkenazi*
- 37 RANKL (Receptor activator of NF $\kappa$ B ligand)  
*Simon Blake and Ian James*
- 38 CD95L/FasL and its receptor CD95 (APO-1/Fas)  
*Marcus E. Peter, Bryan C. Barnhart and Alicia Algeciras-Schimmich*
- 39 HMGB-1  
*Haichao Wang, Christopher Czura and Kevin J. Tracey*

### Subsection E. The Tyrosine Kinase Receptor Signaling Molecules

- 40 Macrophage Colony Stimulating Factor [CSF-1]  
*Michael T. Lotze and John A. Hamilton*
- 41 EGF family ligands  
*David C. Lee, C. Leann Hinkle, Leslie F. Jackson, Shunqiang Li, and Susan Wohler Sunnarborg*
- 42 FLT3 ligands  
*Stewart D. Lyman and Hilary J. McKenna*
- 43 Stem cell factor  
*Ian K. McNiece and Robert A. Briddell*
- 44 Vascular endothelial growth factor  
*Dmitry I. Gabrilovich and Mikhail M. Dikov*

**Subsection F. The Chemokines and other Cell Migration Regulating Factors**

- 45 Macrophage migration inhibitory factor (MIF)  
*Douglas A. Arenberg, and Richard Bucala*
- 46 Interleukin-8 and other CXC chemokines  
*Naofumi Mukaida, Sergey A. Ketlinsky, and Kouji Matsushima*
- 47 CC chemokines  
*Alberto Mantovani, Massimo Locati, and Silvano Sozzani*
- 48 Fractalkine  
*Violetta Zujovic and Jeffrey K. Harrison*

**Subsection G. The TGF Beta Family Members**

- 49 Transforming growth factor  $\beta$   
*Philip H. Howe*
- 50 Inhibin/activin family  
*David J. Phillips*
- 51 Bone morphogenic proteins  
*A. Hari Reddi*

**SECTION III. CLINICAL APPLICATION OF CYTOKINES AND CYTOKINE INHIBITION**

- 52 Autoimmunity and cytokines: pathogenesis and therapy  
*Evangelos Th. Andreacos and Marc Feldmann*
- 53 Cytokines and cancer  
*Megan A. Cooper and Michael A. Caligiuri*
- 54 Interferon  $\alpha$ : biology, pharmacology, and therapy for chronic viral hepatitis  
*Geoffrey M. Dusheiko*
- 55 Haemopoietic cytokines  
*John L. Lewis and Myrtle Y. Gordon*
- 56 Antiangiogenesis and proangiogenic  
*Andrew L. Feldman, Steven K. Libutti*
- 57 Cytokines and transplantation  
*Geetha Chalasani, Fadi G. Lakkis*
- 58 Cytokines and asthma  
*Timothy B. Oriss and Anuradha Ray*
- 59 Cytokine gene transfer  
*Paul D. Robbins, Walter J. Storkus, and Andrea Gambotto*
- 60 Antisense therapy

# Preface to the First Edition

---

Cytokines feature at the forefront of biomedical research. An understanding of their properties is now essential for the immunology student, researcher and teacher and for today's medical practitioner who needs to understand immunologic disease and immunological approaches to therapy. The pace with which this ever-expanding field has developed has been rapid enough to exceed the most optimistic expectations and to bewilder the most assiduous student. Cytokine research is expected to provide the key to pharmacological manipulation of the immune response and commands the attention of a massive and highly focused biotechnology industry. The chapters in this book are a good representation of the areas to which molecular biology has been most successfully applied. Biotechnology companies provide most of the pure, well-characterized cell growth regulatory and effector molecules used in academic and industrial laboratories or in clinical medicine as diagnostic tools or therapeutic agents.

Cytokines represent a sought-after symposium theme in immunology, molecular biology and molecular genetics. The cytokine literature ranges from the most basic to the applied. Unfortunately, technical advances, rapid expansion and diversification have prompted narrower specialization and reduced the ease of communication. The aim of this book is to inform and to provide detailed information and reference material on the many aspects of pure and applied cytokine science. These include the molecular characteristics of cytokines, their genes and receptors, the cellular sources and targets of cytokines, their biological activities and as best can presently be defined, their mechanisms of action. Confronted with such a vast amount of new information, up-to-date coverage is an almost unattainable goal. The scope of cytokine research could only be effectively covered in a multi-authored volume and it is indeed fortunate that each chapter is written by a leading authority(ies). Although many chapters focus on individual cytokines, it is also apparent that aspects such as cell sources, molecular structure, purification and bioassay have many features in common. A certain amount of duplication is, therefore, inevitable. The cytokine network, cytokine interactions, the roles of cytokines in disease pathogenesis and the therapeutic applications of cytokine research are dealt with in detail. In attempting to provide comprehensive coverage, a chapter on phylogeny has been included. The last chapter was commissioned to provide both perspective and a somewhat sobering view of the future.

I am indebted to the many authors around the world who have so generously devoted their knowledge, energy and time to the creation of this book. I also wish to acknowledge the support of Dr Susan King, and her staff at Academic Press in London, whose skill and energy were essential in the genesis of *The Cytokine Handbook*.

Angus W. Thomson

# Preface to the Second Edition

---

In the Preface to the First Edition, it was stated that to produce a book that provided up-to-date coverage of all aspects of the cytokine field was an 'almost unattainable goal'. Since the First Edition went to press in the spring of 1991, advancement both in our knowledge and understanding of the cytokine network has been predictably rapid, fully justifying the publishers' faith in a Second Edition of *The Cytokine Handbook* within 3 years. The original chapters have been revised and updated, and, with few exceptions, this has been undertaken by the original authors. Synthesis of information in the context of the cytokine network has again been a key objective. Every effort has been made to maintain currency and it is in promptly fulfilling this goal that the contributing authors deserve great credit. 'New' cytokines have, of course, emerged and continue to 'appear'. Thus, this new edition features individual chapters on IL-9, IL-10 and IL-12, with a 'stop-press' overview of IL-13 and even newer molecules that are candidates for designation as interleukins IL-14 and IL-15.

What constitutes a new interleukin? The assignation of a new designation depends on several clearly defined criteria, recently established by a sub-committee of the nomenclature committee of the International Union of Immunological Societies (Paul *et al.*, 1992). The criteria laid down include molecular cloning and expression, a unique nucleotide and inferred amino acid sequence, and the availability of a neutralizing monoclonal antibody. Furthermore, the granting of a new interleukin designation requires that the candidate molecule be a natural product of cells of the immune system (defined loosely as lymphocytes, monocytes and other leukocytes). The new interleukin must also mediate a potentially important function in immune responses and exhibit an additional function(s) so that a simple, functional name might not be adequate. Finally, these characteristic features should have been described in a peer-reviewed publication.

This new edition incorporates separate chapters on G-CSF, M-CSF and GM-CSF, whereas in the first edition, only one chapter – on 'colony stimulating factors' – covered the properties of these molecules. A chapter is also now afforded to *TGF- $\beta$* , which exhibits both inhibitory and stimulatory effects on a variety of cell types and is a potent immunosuppressant. Another significant and substantial new chapter concerns 'chemokines'. IL-8 (the 'highest' interleukin designation afforded a separate chapter in the first edition) was the first member of the chemokine family to be identified. More recently, other low molecular weight chemotactic polypeptides have been discovered that play a key role in cell activation and chemotaxis during the inflammatory response. These include RANTES (regulated upon activation, normal *T* expressed and secreted!), macrophage chemotactic and activating factor (MCAF), macrophage inflammatory protein (MIP)-1 $\alpha$  and MIP-1 $\beta$ . All share a conserved, four cysteine motif and can be further subclassified on the spacing of the conserved cysteine residues.

Evaluation of the clinical potential of cytokines is one of the most exciting challenges of contemporary medicine. In addition, and in contradistinction to cytokine or cytokine gene therapy, the emergence of a new class of therapeutic agents, comprising soluble cytokine receptors (e.g. soluble (s) IL-IR, sTNFR, sIFN- $\gamma$ R), receptor antagonists (e.g. IL-1ra) and counter-regulatory cytokines, represents one of the most important developments in the cytokine field in recent years. Successes in the sequencing, cloning and expression of cytokine receptors has facilitated production and evaluation of their therapeutic utility in several acute and chronic cytokine-mediated diseases. This exciting and challenging development is one of the themes covered under the several chapters devoted to therapeutic aspects of cytokine biology.

The last few years have seen the advent of new approaches to interrogating the roles of cytokines *in vivo*. Thus cytokine gene 'knockout' mice and mice transgenic for cytokine gene reporter constructs are likely to provide new knowledge about the *in vivo* role(s) of cytokines, especially in experimental autoimmune disorders, cancer or infectious diseases that may be difficult to mimic satisfactorily *in vivo*. The molecular genetics of cytokines (reviewed in Chapter 2) is yet another new and exciting aspect of this key field of contemporary molecular biology and medicine that has provided the impetus for the second edition of *The Cytokine Handbook*. Those who acquire knowledge by reading this book, or who are stimulated by the implications of the recent developments described herein, owe thanks to the many experts around the world who have so generously given of their valuable time, energy and expertise. The cordial and enthusiastic support of these scientists and clinicians has been an impelling influence that would be difficult to overrate. I am indebted to my colleague Dr Mike Lotze for constructive suggestions, Ms Shelly Conklin for valuable secretarial help and to Dr Tessa Picknett and her colleagues at Academic Press in London for their resolute support and guidance in ensuring that the notion of a second edition became a tangible reality.

# Preface to the Third Edition

---

As the Third Edition goes to press, the stream of cytokine discovery flows unabated. We are confronted by description after description of novel cytokine-controlled systems of cell differentiation and proliferation and of the role of cytokines in immune regulation. In order to keep pace with these developments, this new edition of *The Cytokine Handbook* has been completely revised and updated. The contributors are largely the same body of devoted international authorities, with several notable new additions. Amongst the newcomers to the extensive panoply of cytokines covered in this edition are the recently designated interleukins (IL)-16 (formerly lymphocyte chemotactic factor), IL-17 (identified originally as cytotoxic T lymphocyte antigen-8) and IL-18 (interferon- $\gamma$  inducing factor). The daunting expansion of new information is perhaps better illustrated by the 'explosion' of chemokines. About sixty distinct human chemokine gene products have been identified to date. Regarded historically as regulators of leukocyte trafficking, chemokines have recently made a major impact in the area of infectious disease, including dramatic new understanding that chemokine receptors are at the center of HIV pathogenesis. Just two examples of chemokines that have recently come to prominence are eotaxin (the CCR-3 receptor-specific, eosinophil-selective chemokine) and the structurally unique fractalkine, with intrinsic adhesion and chemotactic activities. Two chapters are now devoted to the vastly expanding area of chemokines and their receptors.

The Third Edition sees individual chapters afforded to IL-1 through IL-15, with the exception of IL-14, reflecting the current uncertainty about the identity of the IL-14 molecule. The TNF-related cytokine-receptor superfamily of secreted and membrane-bound ligands that includes TNF/lymphotoxin ( $\alpha/\beta$ , CD40, Fas and 4-1BB systems, now appears to have important functional roles in the immune response. Each member is paired with a specific cell surface receptor(s) that, together, form a corresponding family of receptors. Recent studies have revealed important and unique roles of the TNF-related ligands and receptors that are covered in an additional new chapter.

In addition to coverage of the colony-stimulating factors G-, M- and GM-CSF, two new chapters in this edition are afforded to individual hematopoietic cytokines – stem cell factor (SCF) (c-kit ligand) and flt-3 ligand – that have many biological functions in common. SCF is a potent costimulatory or synergistic factor in cytokine cocktails for manipulation of hematopoietic cells. It appears to be of value in the combination of *ex vivo* 'expansion' technologies with gene transfer methods for the correction of genetic disease or the support of multiple chemotherapy cancer patients. The recently cloned cytokine flt-3 ligand has been shown to dramatically increase the numbers of functional dendritic cells and also to increase natural killer cells *in vivo*. Moreover it exerts anti-tumor activity, raising expectation of a future role of this molecule as a human immunotherapeutic agent.

Therapeutic applications of cytokines are now covered in detail in several chapters, including a new chapter on cytokine gene therapy. The first therapeutic cytokine gene transfer study began several years ago in patients with advanced malignancy; now numerous trials have been approved for the transfer of cytokine genes to tumor cells, tumor-infiltrating lymphocytes, blood lymphocytes, or fibroblasts. A few studies involve the use of cytokine genes for the treatment of non-malignant conditions, such as rheumatoid arthritis. A new chapter in this edition reviews progress in cytokine gene therapy.

As in the two previous editions, valuable up-to-date practical information is included in the extensive account of cytokine assays. The phylogeny of cytokines has become such a growth area that the information can barely be contained in a single chapter.

I am again immensely indebted to the many experts around the world who have made this new edition possible. On the home front, my colleague Dr Mike Lotze has been a constant source of creative suggestions and lively discussion. My thanks are due once again to Dr Tessa Picknett, senior editor, and also to Mr Duncan Fatz and Ms Emma White at Academic Press in London, and to Ms Shelly Conklin for invaluable secretarial assistance.

*Angus W. Thomson*

# Preface to the Fourth Edition

---

It is also said that Sisyphus, being near to death, rashly wanted to test his wife's love. He ordered her to cast his unburied body into the middle of the public square. Sisyphus woke up in the underworld. And there, annoyed by an obedience so contrary to human love, he obtained from Pluto permission to return to earth in order to chastise his wife. But when he had seen again the face of this world, enjoyed water and sun, warm stones and the sea, he no longer wanted to go back to the infernal darkness. Recalls, signs of anger, warnings were of no avail. Many years more he lived facing the curve of the gulf, the sparkling sea, and the smiles of earth. A decree of the gods was necessary. Mercury came and seized the impudent man by the collar and, snatching him from his joys, led him forcibly back to the underworld, where his rock was ready for him.

**The Myth of Sisyphus, Albert Camus; 1940.**

Camus was awarded the Nobel Prize for Literature in 1957 for his existentialist contributions to finding order and meaning for man living in a world absurd and, at the time he wrote it, wracked by war. The notion of a mortal committed to daily striving to move his rock uphill serves as a suitable metaphor for cytokines, literally cell movers. At some level it also mirrors the profound labors of our contributors who, in each edition, find the energy to move their chapters a bit closer to the apogee of fuller understanding and bounded exposition. If this work is at all successful, it is because of them and their professorial stance to organizing what is becoming almost an impossibly large set of contributions to the literature.

Astute observers will find this fourth edition substantially altered, now in two volumes, organized around cytokine families, many of them revealed by the availability of new sequence data arising from the human genome project. It also introduces quotes chosen in most part by the author of each chapter and denoting some of the personal affectations of each contributor. It has striven to be complete and still readable allowing access to the considerable literature now available for many of these factors which, Mercury-like, bring and move cells to their appointed fate. The final section knits together the individual cytokines into the clinical implications and, in some instances, applications of cytokines. The hope is that some of them might find their way singly, or most often, in pairs, into useful recombinant pharmaceutical agents. Since the last edition, interleukin 1 receptor antagonist (IL-1RA) has

been approved for the therapy of rheumatoid arthritis (Schiff, 2000). The successful application of TNF antagonists in chronic inflammatory conditions continues to expand with what we suspect will be an increasing number of indications moving beyond arthritis (Criscione and St Clair, 2002) and inflammatory bowel disease to other difficult clinical problems. Up to the moment of press, we have been cognizant of new molecules and new insights and have incorporated these with assistance and support of our editor up to the recently identified IL-28 and IL-29! (Kotenko *et al.*, 2002; Sheppard *et al.*, 2002).

Some of the major advances captured in this edition beyond those made possible by the availability of the full human and mouse genome represent the increased power of new technology. These include application of quantitative polymerase chain reaction (PCR) assessment of cytokines (Walker, 1998; Gulletti *et al.*, 2001; Rajeevan *et al.*, 2001), availability of measurement of multiple cytokines in ELISpot assays (Bennouna *et al.*, 2002; Leong *et al.*, 2002; Meidenbauer *et al.*, 2002; Scheibenbogen *et al.*, 2002; Shmitz *et al.*, 2002) as well as microarrays (Benson *et al.*, 2002; Cappellen *et al.*, 2002) allowing careful evaluation of the downstream messages induced by cytokines and chemokines. The proteomic analysis and patterning of individual cytokines *in vitro* and *in vivo* is less fully developed (Petricoin *et al.*, 2002; Schweitzer *et al.*, 2002) but by the time of the fifth edition is expected to allow greater analysis of the complexity of cell communication mediated by cytokines. Also the deeper understanding of individual cells or cell mixtures has been made possible by the development of so-called high content screening using integrated high resolution fluorescence microscopy, data algorithm development and display and automation (Ghosh *et al.*, 2000; Taylor *et al.*, 2001). We anticipate that studying cells interacting with each other will provide a wealth of additional information, as yet only modestly pursued in the available literature.

We would like to dedicate this edition of *The Cytokine Handbook* to our colleagues, the scientists laboring within academe and the biotechnology/pharmaceutical industries. Like Sisyphus and his spouse, they have to work long hours, often together, to move their chosen cytokine or chemokine closer to a fuller understanding and ultimate utility in discerning the biology writ large by their production, in full display within the public square. It is our expectation that within the bounds of creating new knowledge and creating value, that application of this knowledge might improve human health and the common weal. Finally to Shelly Conklin who organized our manuscripts dutifully as they each arrived, to Bridget Colvin for her scholarly contribution to the quotes, and to Jacqueline Read who together with Tessa Picknett as our editors, made the task of developing this edition more joyful than if it were in less able hands, we offer our humble appreciation and thanks.

Michael T. Lotze

# Foreword to the Fourth Edition

---

## *What are cytokines?*

As so aptly discussed by Jan Vilcek in the introductory chapter to this book, *The Cytokine Handbook*, cytokines are regulatory peptides that can be produced by every nucleated cell type in the body. Cytokines have pleiotropic regulatory effects on haematopoietic and many other cell types that participate in host defense and repair processes. Cytokines therefore include lymphocyte-derived factors known as 'lymphokines', monocyte-derived factors called 'monokines', haematopoietic 'colony stimulating factors', connective tissue 'growth factors', and chemotactic chemokines.

## *Why do cytokines exist?*

The evolution of large multicellular organisms require the development of intercellular messengers such as hormones, neuropeptides and cytokines to permit marshalling of co-ordinated cellular responses. It has been proposed that the structural homology between adhesion proteins that mediate cell-contact-dependent interactions and cytokine ligands, suggests that soluble cytokines evolved from cell-associated signals (Grumet *et al.*, 1991). In fact, a number of cytokines and their receptors exist in both soluble (shed) and cell-associated form and can have different functional consequences in each state.

## *How are cytokines different from hormones?*

Endocrine hormones, which are generally produced by specialized glands, are present in the circulation and serve to maintain homeostasis. In contrast, most cytokines usually act over short distances as autocrine or paracrine intercellular signals in local tissues and – with the exception of macrophage colony-stimulating factor (M-CSF), stem cell factor, erythropoietin and a latent form of the transforming growth factor  $\beta$  (TGF $\beta$ ) – only occasionally spill over into the circulation and initiate systemic reactions. Except for the above, cytokines generally are not produced constitutively, but are generated in response to danger signals to contend with challenges to the integrity of the host. The functions of cytokines are distinct from those of hormones, since they serve to maintain homeostasis by regulating innate host defense and the immune system, through damage control and by promotion of reparative processes.

## *How did lymphokines come to be discovered?*

The possibility that cell-derived factors mediate biological activities was first suggested by experiments carried out by Rich and Lewis (1932). They observed that migration of neutrophils and macrophages in
